Acknowledgement

This research is partially funded by the **SecureChange** EU FP7 project, the **Interuniversity Attraction Poles** Programme of the Belgian Science Policy, and by the **Research Fund K.U.Leuven**

Context

Idea: Change Patterns

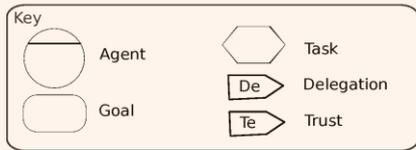

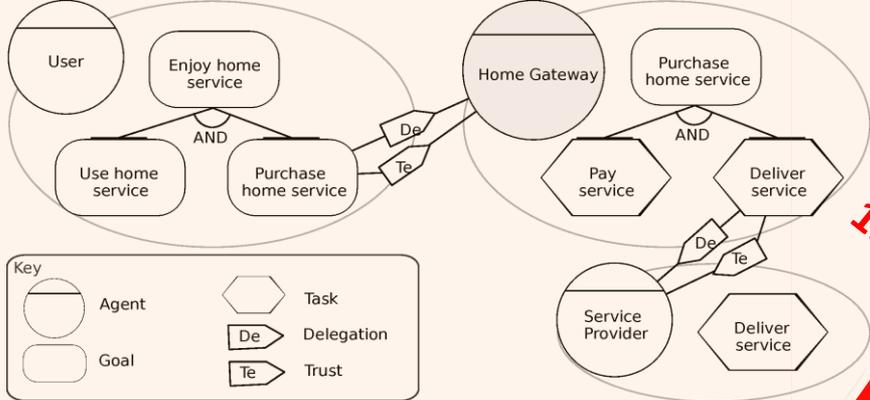

- Prepare a stable architecture at dev-time
 - Based on foreseen scenarios
 - Assuming limited development resources
 - According to a model-based approach
- Evolve when necessary
 - Avoid high-impact changes
 - Supported by automation
- Trade-off 'now' vs. 'later' (necessary vs. too much)

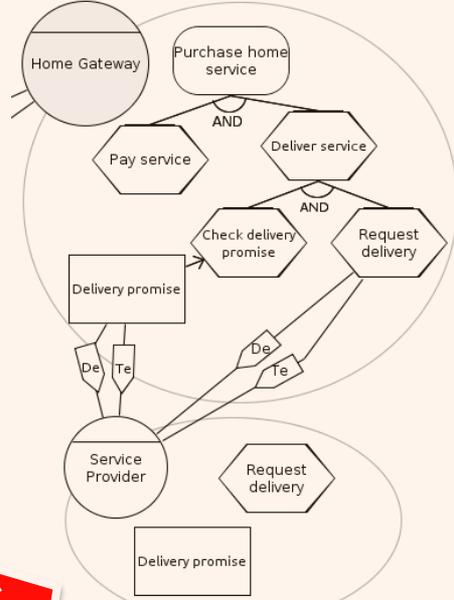

Outline

- **Change Patterns** explained
- Empirical **validation**
 - Has shown that CP bring value to the table
- **Problem**: do CP exists in nature?
 - Learning from “in vivo” experiment

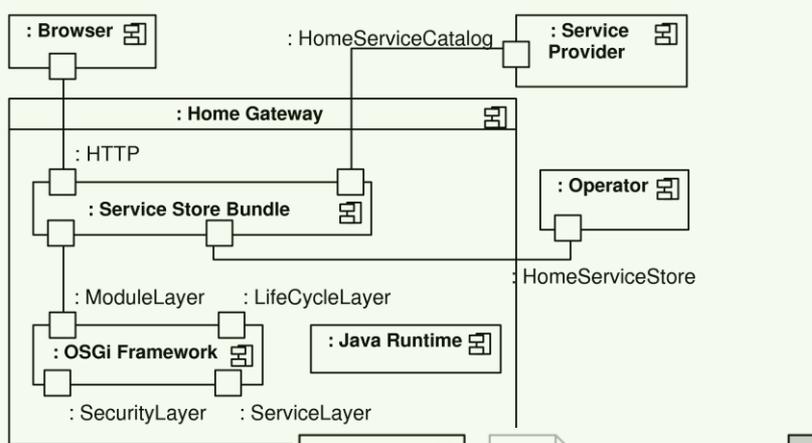

1. Scenario

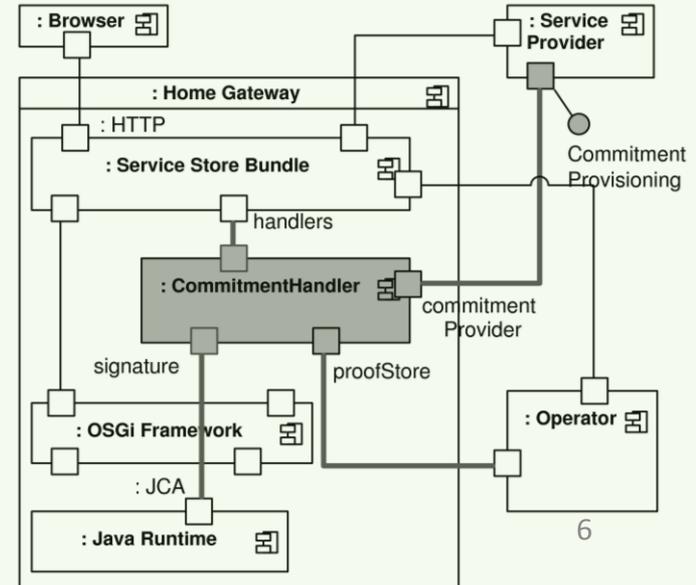

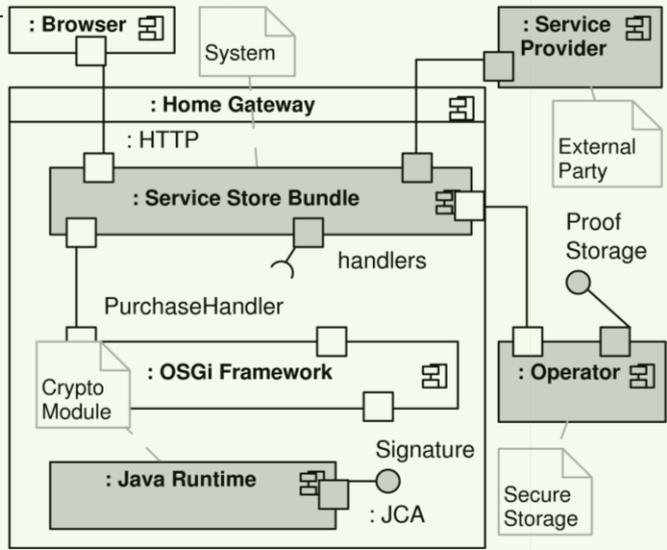

4. Feedback

2. Preparation

3. Evolution

Tool support (Eclipse plugin)

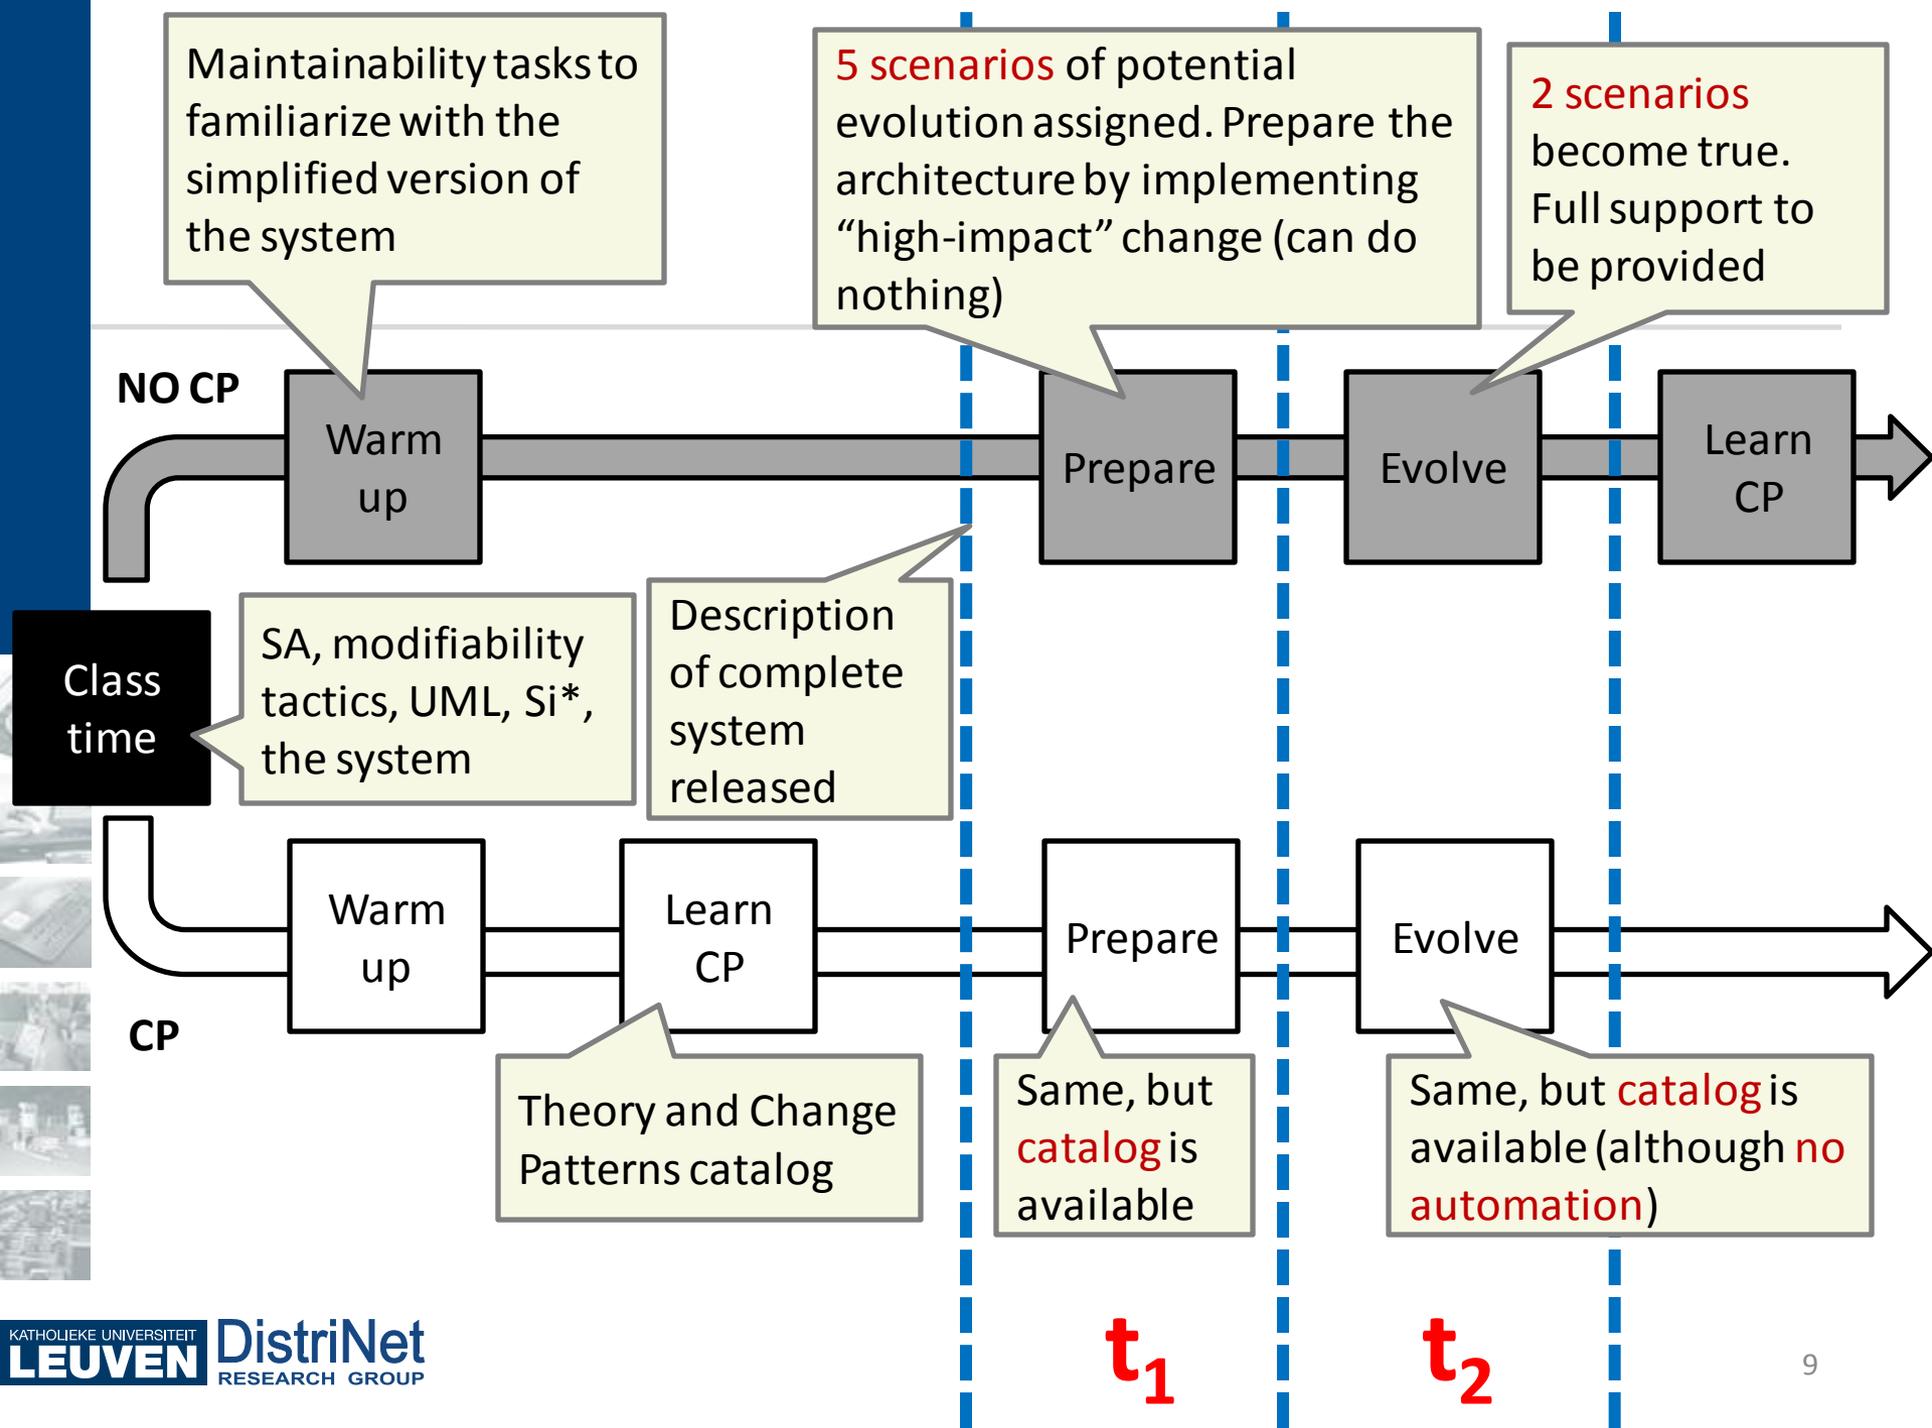

The image shows a screenshot of an Eclipse plugin interface. On the left, a window titled "Found matches" displays a list of matches for three patterns. The first match, "ChangeScenarioInstance 0/1. Evolving trust of execution upon external actor", is selected. Below the list, a text area shows the message: "Actor 'Home Gateway' no longer trusts the execution of Task 'Deliver service' by actor 'Service provider'." A "Show match details" button is visible.

In the foreground, an "Assess change" dialog box is open. It contains the following text: "Assess the following change" and "Review the following changeScenarioInstance of change pattern '1. Evolving trust of execution upon external actor', and accept or reject it based on its relevance, likelihood and importance." Below this, there are two side-by-side lists of elements. The left list includes: "Actor Home Gateway", "Actor Service provider", "[De] Deliver service : Actor Home Gateway -> Actor Service provider", "[Te] Deliver service : Actor Home Gateway -> Actor Service provider", and "Task Deliver service". The right list includes: "Actor Home Gateway", "Actor Service provider", "[De] Deliver service : Actor Home Gateway -> Actor Service provider", "[Se] Deliver service : Actor Home Gateway -> Actor Service provider", and "Task Deliver service". The "[Te] Deliver service" item in the left list and the "[Se] Deliver service" item in the right list are highlighted.

At the bottom of the dialog, there are three checkboxes: "Only show the part of the model that matches with the change pattern" (checked), "Show change model" (unchecked), and "Show properties" (unchecked). Below these, a text area displays the message: "Actor 'Home Gateway' no longer trusts the execution of Task 'Deliver service' by actor 'Service provider'." At the bottom right, there are "Accept" and "Reject" buttons.

CONTROLLED EXPERIMENT

Test hypotheses

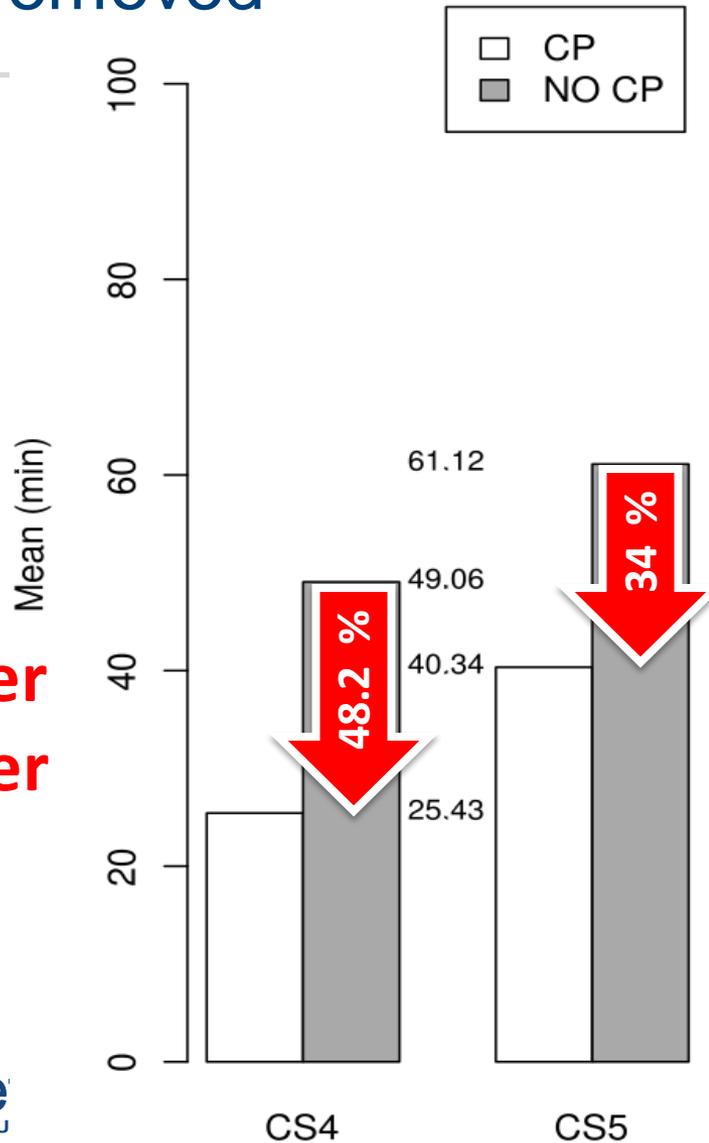

- H0' The average combined effort of preparing and evolving the architecture ($\mu_{t_1+t_2}$) is the same in the control group (NO CP) and the treatment group (CP)
- H0'' The average effort to evolve the architecture (μ_{t_2}) is the same in the control group (NO CP) and the treatment group (CP)
- Tool instrumented for activity monitoring
 - The tool logs a timestamp whenever an editor is opened/closed

Results

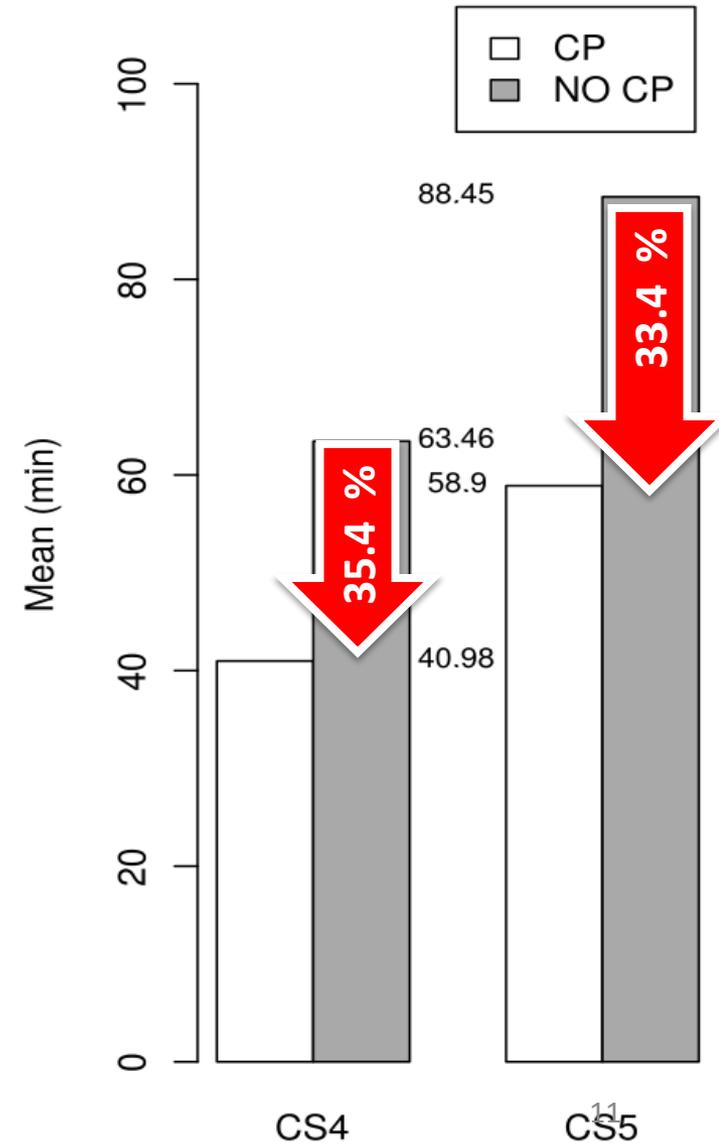

Outliers removed

The lower
the better

(effort to evolve)
T2

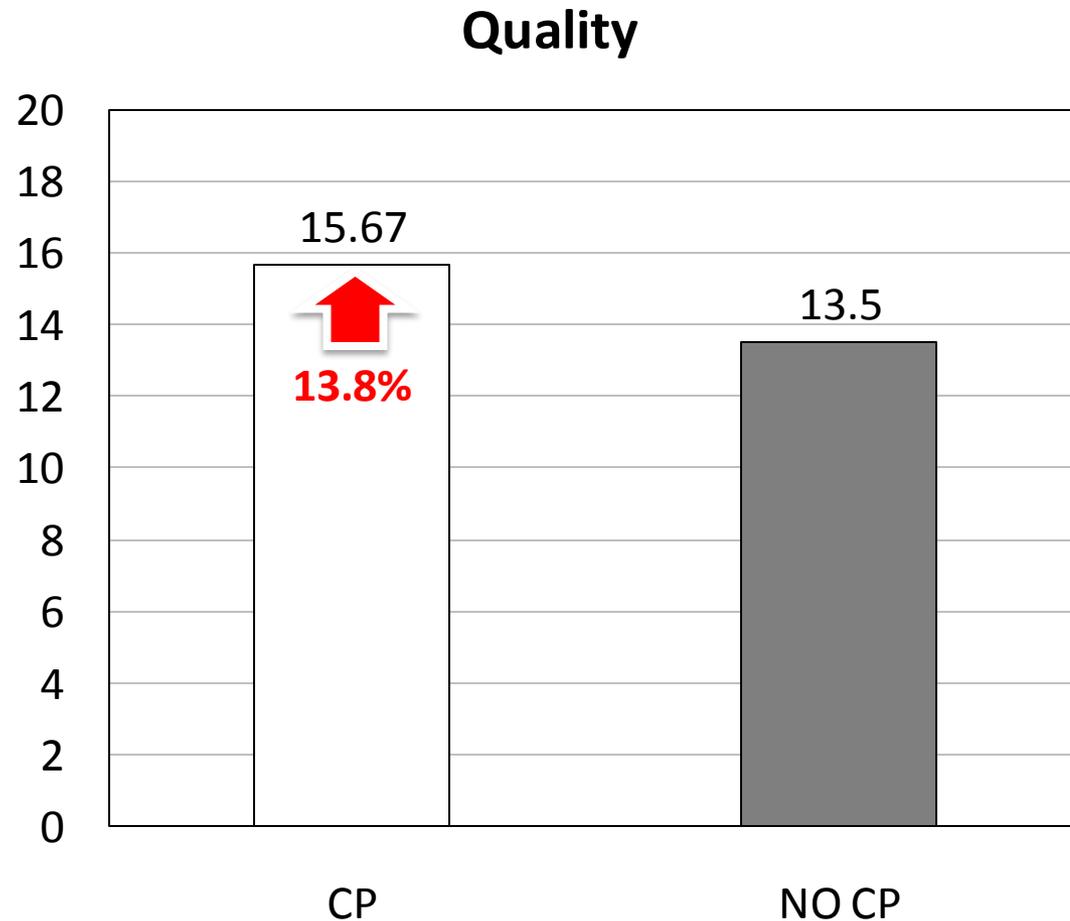

(combined effort)
T1 + T2

Overall quality

The higher
the better

LEARNING

Do CPs exist in nature?

- Patterns are not invented, they are discovered
- Mining (open) software repositories not feasible
 - Documentation of SW architecture non-existing
 - Extraction is witchcraft (been there, done that!)
 - We need both reqs and archi deltas
- Alternative: put together a pool of designers and observe how they react to change requests, in a **controlled experiment**

Experiment design (tentative)

- Give a UML description of an architecture to **N participants**
 - Assign a number of change requests (same to each)
 - Collect the **resulting artifacts** (updated UML diagrams)
 - In a nutshell, the artifacts are **graphs**
 - **Cluster** the artifacts according to a **distance function** (*similarity*)
 - Label clusters (wrong, naïve/intuitive, pattern candidate)
-
- Some initial data already available (the control group of previous experiment)
 - Only 5 data points... good for a **pilot**?

Open questions

- What techniques for clustering? **Ontology matching?**
- Similarity function? **Structure + lexicographic + semantic?**
- What **size of experiment** do I need for the techniques to work?
 - N=16 PhD students vs. N=100 Master students
