Abstract

In a recent line of research, two familiar concepts from logic programming semantics (unfounded sets and splitting) were extrapolated to the case of epistemic logic programs. The property of epistemic splitting provides a natural and modular way to understand programs without epistemic cycles but, surprisingly, was only fulfilled by Gelfond’s original semantics (G91), among the many proposals in the literature. On the other hand, G91 may suffer from a kind of self-supported, unfounded derivations when epistemic cycles come into play. Recently, the absence of these derivations was also formalised as a property of epistemic semantics called foundedness. Moreover, a first semantics proved to satisfy foundedness was also proposed, the so-calledFounded Autoepistemic Equilibrium Logic (FAEEL). In this paper, we prove that FAEEL also satisfies the epistemic splitting property something that, together with foundedness, was not fulfilled by any other approach up to date. To prove this result, we provide an alternative characterisation of FAEEL as a combination of G91 with a simpler logic we called Founded Epistemic Equilibrium Logic (FEEL), which is somehow an extrapolation of the stable model semantics to the modal logic S5.

KEYWORDS: Answer Set Programming, Epistemic Specifications, Epistemic Logic Programs

1 Introduction

The language of epistemic specifications (Gelfond 1991) or epistemic logic programs extends disjunctive logic programs, under the stable model (Gelfond and Lifschitz 1988) semantics, with modal constructs called subjective literals. These constructs allow to check whether a regular or objective literal l is true in every stable model (written K l) or in some stable model (written M l) of the program. For instance, the rule:

\[ a \leftarrow \neg \text{K} b \]  

means that a should be derived whenever we cannot prove that all the stable models contain b. The definition of a “satisfactory” semantics for epistemic specifications has proven to be a non-trivial enterprise with a long list of alternative semantics (Gelfond 1991; Wang and Zhang 2005; Truszczyński 2011; Gelfond 2011; Fariñas del Cerro et al. 2015; Kahl et al. 2015; Shen

∗ This work has been partially supported by the Centre International de Mathématiques et d’Informatique de Toulouse (CIMI) through contract ANR-11-LABEX-0040-CIMI within the programme ANR-11-IDEX-0002-02 and the Alexander von Humboldt Foundation.
and Eiter 2017; Cabalar et al. 2019a). The main difficulty arises because subjective literals query
the set of stable models but, at the same time, occur in rules that determine those stable models.
As an example, the program consisting of:

\[ b \leftarrow \neg K_a \]  

(2)

plus the above rule (1) has now two rules defining atoms \( a \) and \( b \) in terms of the presence of
those same atoms in all the stable models. To solve this kind of cyclic interdependence, the
original semantics by Gelfond (1991) (G91) considered different alternative world views or sets
of stable models. In the case of program (1)-(2), G91 yields two alternative world views\(^1\), \([\{a\}]\)
and \([\{b\}]\), each one containing a single stable model, and this is also the behaviour obtained in the
remaining approaches developed later on. As noted by (Truszczyński 2011), the feature that made
G91 unconvincing, though, was the generation of self-supported world views. A prototypical
example for this effect is the epistemic program consisting of the single rule:

\[ a \leftarrow K_a \]  

(3)

whose world views under G91 are \([\emptyset]\) and \([\{a\}]\). The latter is considered as counter-intuitive by
all authors\(^2\) because it relies on a self-supported derivation: \( a \) is derived from \( \neg K_a \) by rule (3),
but the only way to obtain \( \neg K_a \) is rule (3) itself. Recently, Cabalar et al. (2019a) proposed to
characterise these unintended world views by extending the notion of unfounded sets (Gelder
et al. 1991) from standard disjunctive logic programs (Leone et al. 1997) to the case of epistemic
logic programs. In that work, the authors also provided a new semantics, called Founded
Autoepistemic Equilibrium Logic (FAEEL), that fulfills that requirement. In fact, FAEEL-world
views are precisely those G91-world views that are founded, that is, those that do not admit any
unfounded set.

On the other hand, it is obvious that programs without epistemic cycles (i.e. cycles involving
epistemic literals) cannot have self-supported derivations. In this sense, one could expect that
proposals that tried to get rid of G91 self-supported derivations coincided with the latter, at least,
for epistemically acyclic programs. However, (Lecrerc and Kahl 2018) have recently pointed out
that this is not the case: for instance, while in G91, (purely) epistemic constraints always remove
world views, this does not hold in other semantics. Watson (2000) and Cabalar et al. (2018;
2019b) went a step farther defining a property called epistemic splitting which, not only defines
an intuitive behaviour for stratified epistemic specifications, but also extends the splitting theo-
rem, well-known for autoepistemic logic (Gelfond and Przymusinska 1992) and standard logic
programs (Lifschitz and Turner 1994), to the case of epistemic logic programs. For instance, if
we consider a program consisting of rules (1)-(2) plus

\[ c \leftarrow K_a \]  

(4)

we may expect to obtain the world views \([\{a,c\}]\) and \([\{b\}]\) resulting from adding the atom \( c \)
only to the belief sets of the world view that satisfies \( K_a \). This property is known to be satis-
fied by the G91 semantics, but surprisingly not for those that tried to correct its self-supported
problem (Cabalar et al. 2018; Cabalar et al. 2019b).

The major contribution of this paper is the proof that FAEEL satisfies the epistemic splitting

---

\(^1\) For the sake of readability, sets of propositional interpretations are embraced with \([\;]\) rather than \{ \}.

\(^2\) This includes Gelfond himself, who proposed a new variant in (Gelfond 2011) motivated by this same example and
further modified this variant later on in (Kahl et al. 2015).
Founded (Auto)Epistemic Equilibrium Logic Satisfies Epistemic Splitting

property as defined in (Cabalar et al. 2018; Cabalar et al. 2019b). Joining this result with the already known fact that this semantics also satisfies the foundedness property shows that FAEEL is a solid candidate to serve as a semantics of epistemic logic programs. A second contribution of this paper is the introduction of a logic that we call Founded Epistemic Equilibrium Logic (FEEL) and which can be intuitively seen as the combination of the Equilibrium Logic with the modal logic S5. For the sake of comparative, FAEEL corresponds to the combination of the Equilibrium Logic with the Moore’s Autoepistemic Logic (AEL; Moore 1985). In this sense, FEEL is the combination of a non-monotonic logic with a monotonic one, while FAEEL is the combination of two non-monotonic logics, a fact that makes FEEL much easier to study. This bring us to the third contribution of the paper: FAEEL world views can be precisely characterised as those G91 world views that are at the same time FEEL world views. This allows us to study FAEEL properties by studying them independently in FEEL and G91 and then combining their results. This is precisely the methodology used in proving the epistemic splitting theorem for FAEEL.

The rest of the paper is organised as follows. Section 2 revisits the background knowledge about equilibrium logic, epistemic specifications, the epistemic splitting property and FAEEL necessary for the rest of the paper. Section 3 introduces FEEL and studies the relation between this logic and FAEEL. In Section 4, we study the epistemic splitting property in FEEL and FAEEL and, in Section 5, we discuss other existent approaches to epistemic logic programs. Finally, Section 6 concludes the paper.

2 Background

We start by recalling the basic definitions needed for the rest of the paper. Given a set of atoms $At$, an (epistemic) formula is defined according to the following grammar:

$$\varphi ::= \bot \mid a \mid \varphi_1 \land \varphi_2 \mid \varphi_1 \lor \varphi_2 \mid \varphi_1 \rightarrow \varphi_2 \mid K\varphi \quad \text{for any atom } a \in At.$$ 

In our context, the epistemic reading of $K\psi$ is that “$\psi$ is one of the agent’s beliefs.” Thus, a formula $\varphi$ is said to be subjective if all its atom occurrences (having at least one) are in the scope of $K$. Analogously, $\varphi$ is said to be objective if $K$ does not occur in $\varphi$. For instance, $\neg Ka \lor Kb$ is subjective, $\neg a \lor b$ is objective and $\neg a \land Kb$ none of the two. Given a formula $\varphi$, by $Atoms(\varphi)$ we denote the set of all atoms occurring in $\varphi$. For instance, $Atoms(\neg a \lor Kb) = \{a, b\}$. As usual we define the following derived operators: $\varphi \leftrightarrow \psi \equiv (\varphi \rightarrow \psi) \land (\psi \rightarrow \varphi)$, $\varphi \iff (\varphi \rightarrow \bot)$ and $\top \equiv \bot$. An (epistemic) theory is a (possibly infinite) set of formulas as defined above and an objective theory is a theory whose formulas are objective. We write $Atoms(\varphi)$ to represent the set of atoms occurring in any formula $\varphi$ and $Atoms(\Gamma)$ to represent the set of atoms occurring in any theory $\Gamma$. Recall that (Gelfond 1991) included a second subjective operator $M$ such that $Ml$ is readed as “the agent believes that $l$ is possible.” In this paper, we assume here that $M\varphi$ is just an abbreviation$^3$ for $\neg K\neg \varphi$.

2.1 Equilibrium Logic and the Stable Models Semantics

A propositional interpretation $T$ is a set of atoms $T \subseteq At$. We write $T \models \varphi$ to represent that $T$ classically satisfies formula $\varphi$. An HT-interpretation is a pair $\langle H, T \rangle$ (respectively called “here”

$^3$ Several interpretations of $M$ are possible in the logics considered in this paper depending on the level of foundedness that it is expected to satisfy. We limit ourselves here to the simplest interpretation of $M$, leaving other interpretations for a more detailed discussion in the future.
and “there”) of propositional interpretations such that \( H \subseteq T \subseteq At \); it is said to be total when \( H = T \). We write \( \langle H, T \rangle \models \varphi \) to represent that \( \langle H, T \rangle \) satisfies a formula \( \varphi \) under the recursive conditions:

- \( \langle H, T \rangle \models \bot \)
- \( \langle H, T \rangle \models p \text{ iff } p \in H \)
- \( \langle H, T \rangle \models \varphi \land \psi \text{ iff } \langle H, T \rangle \models \varphi \text{ and } \langle H, T \rangle \models \psi \)
- \( \langle H, T \rangle \models \varphi \lor \psi \text{ iff } \langle H, T \rangle \models \varphi \text{ or } \langle H, T \rangle \models \psi \)
- \( \langle H, T \rangle \models \varphi \rightarrow \psi \text{ iff both } (i) T \models \varphi \rightarrow \psi \text{ and } (ii) \langle H, T \rangle \nvdash \varphi \text{ or } \langle H, T \rangle \models \psi \)

As usual, we say that \( \langle H, T \rangle \) is a model of a theory \( \Gamma \), in symbols \( \langle H, T \rangle \models \Gamma \), iff \( \langle H, T \rangle \models \varphi \) for all \( \varphi \in \Gamma \). It is easy to see that \( \langle T, T \rangle \models \Gamma \text{ iff } T \models \Gamma \) classically. For this reason, we will identify \( T, T \) simply as \( T \) and will use \( \models \) indistinctly. Interpretation \( \langle T, T \rangle = T \) is a stable (or equilibrium) model of a theory \( \Gamma \) iff \( T \models \Gamma \) and there is no \( H \subset T \) such that \( \langle H, T \rangle \models \Gamma \). We write \( \text{SM} \Gamma \) to stand for the set of all stable models of \( \Gamma \).

### 2.2 G91 semantics for epistemic theories

To represent the agent’s beliefs, we will use a set \( \mathbb{W} \) of propositional interpretations. We call belief set to each element \( I \in \mathbb{W} \) and belief view the whole set \( \mathbb{W} \). The difference between belief and knowledge is that the former may not hold in the real world. Thus, satisfaction of formulas will be defined with respect to an interpretation \( I \subseteq At \), possibly \( I \not\in \mathbb{W} \), that accounts for the real world: the pair \( (\mathbb{W}, I) \) is called belief interpretation (or interpretation in modal logic KD45).

Modal satisfaction is also written \( \mathbb{W}, I \models \varphi \) (ambiguity is removed by the interpretation on the left) and follows the conditions:

- \( \mathbb{W}, I \nvdash \bot \)
- \( \mathbb{W}, I \models a \text{ iff } a \in I \), for any atom \( a \in At \)
- \( \mathbb{W}, I \models \psi_1 \land \psi_2 \text{ iff } \mathbb{W}, I \models \psi_1 \text{ and } \mathbb{W}, I \models \psi_2 \)
- \( \mathbb{W}, I \models \psi_1 \lor \psi_2 \text{ iff } \mathbb{W}, I \models \psi_1 \text{ or } \mathbb{W}, I \models \psi_2 \)
- \( \mathbb{W}, I \models \psi \rightarrow \psi_2 \text{ iff } \mathbb{W}, I \nvdash \psi_1 \text{ or } \mathbb{W}, I \models \psi_2 \) and
- \( \mathbb{W}, I \models \mathbf{K} \psi \text{ iff } \mathbb{W}, J \models \psi \text{ for all } J \in \mathbb{W} \).

Notice that implication here is classical, that is, \( \varphi \rightarrow \psi \) is equivalent to \( \neg \varphi \lor \psi \) in this context. A belief interpretation \( (\mathbb{W}, I) \) is a belief model of \( \Gamma \) iff \( \mathbb{W}, I \models \varphi \) for all \( \varphi \in \Gamma \) and all \( J \in \mathbb{W} \). We say that \( \mathbb{W} \) is an epistemic model of \( \Gamma \), and abbreviate this as \( \mathbb{W} \models \Gamma \), iff \( \mathbb{W}, J \models \varphi \) for all \( \varphi \in \Gamma \) and all \( J \in \mathbb{W} \). Belief models defined in this way correspond to modal logic KD45 whereas epistemic models correspond to S5.

**Example 1.** Take the theory \( \Gamma_1 = \{ \neg \mathbf{K} b \rightarrow a \} \) corresponding to rule (1). An epistemic model \( \mathbb{W} \models \Gamma_1 \) must satisfy: \( \mathbb{W}, J \models \mathbf{K} b \) or \( \mathbb{W}, J \nvdash a \), for all \( J \in \mathbb{W} \). We get three epistemic models from \( \mathbf{K} b \), \( \{b\} \), \( \{a, b\} \), and \( \{b\} \). The rest of cases must force a true, so we also get \( \{a\} \) and \( \{a\}, \{a, b\} \). In other words, \( \Gamma_1 \) has the same epistemic models as \( \mathbf{K} b \lor \mathbf{K} a \).

Note that rule (1) alone did not seem to provide any reason for believing \( b \), but we got three epistemic models above satisfying \( \mathbf{K} b \). Thus, we will be interested only in some epistemic models (that as usual we will call world views) that minimize the agent’s beliefs in some sense. To define such a minimization we rely on the following syntactic transformation that extend the one given by (Truszczynski 2011) by stating an explicit signature in which it is applied. The explicit signature will be useful later on to define the epistemic splitting property.
Definition 1 (Subjective reduct). The subjective reduct of a theory $\Gamma$ with respect to a set of belief views $\mathcal{W}$ and a signature $U \subseteq At$, also written $\Gamma_1^\mathcal{W}$, is obtained by replacing each maximal subjective formula of the form $K \phi$ with $\text{Atoms}(\phi) \subseteq U$ by $\top$ if $\mathcal{W} \models K \phi$; or by $\bot$ otherwise. When $U = \text{At}$ we just write $\Gamma_1^\mathcal{W}$.

Finally, we impose a fixpoint condition where each belief set $I \in \mathcal{W}$ is required to be a stable model of the reduct, obtaining thus the G91 semantics.

Definition 2 (G91 world view). A belief view $\mathcal{W}$ is called a G91-world view of $\Gamma$ if and only if it satisfies $\mathcal{W} = \text{SM}[\Gamma_1^\mathcal{W}]$.

Example 2 (Example 1 continued). Take any $\mathcal{W}$ such that $\mathcal{W} \models Kb$. Then, $\Gamma_1^\mathcal{W} = \{ \bot \rightarrow a \}$ with $\text{SM}[\Gamma_1^\mathcal{W}] = \{ \top \}$. The empty set does not satisfy $Kb$ so $\mathcal{W}$ cannot be a G91-world view of $\Gamma_1$.

If $\mathcal{W} \models Kb$ instead, we get $\Gamma_1^\mathcal{W} = \{ \top \rightarrow a \}$, whose unique stable model is $\{ a \}$. As a result, $\mathcal{W} = \{ \{ a \} \}$ is the unique G91-world view.

Example 3 (Example 2 continued). Let now $\Gamma_2 = \{ \neg Kb \rightarrow a, \neg Ka \rightarrow b \}$ corresponding to rules (1)-(2). Take any $\mathcal{W}$ such that $\mathcal{W} \models \neg Ka \land Kb$. Then, $\Gamma_1^\mathcal{W} = \{ \bot \rightarrow a, \top \rightarrow b \}$ and we have $\text{SM}[\Gamma_1^\mathcal{W}] = \{ \{ b \} \}$. Since $\mathcal{W} = \{ \{ b \} \}$ satisfies $\neg Ka \land Kb$, this is a G91-world view of $\Gamma_2$. If $\mathcal{W} \models Ka \land Kb$ instead, we get $\Gamma_1^\mathcal{W} = \{ \top \rightarrow a, \bot \rightarrow b \}$, whose unique stable model is $\{ a \}$. As a result, $\mathcal{W} = \{ \{ a \} \}$ is also the other G91-world view of $\Gamma_2$. To see that there is not any other world views, note that $\mathcal{W} \models \neg Ka \land Kb$ implies that $\Gamma_2^\mathcal{W} = \{ \top \rightarrow a, \top \rightarrow b \}$ and $\text{SM}[\Gamma_2^\mathcal{W}] = \{ \{ a, b \} \}$. So this cannot be a G91-world view. Similar, it can be checked that no world view can satisfy $Ka \land Kb$.

Example 4. Take now the theory $\Gamma_3 = \{ Ka \rightarrow a \}$ corresponding to rule (3). If $\mathcal{W} \models Ka$ we get $\Gamma_1^\mathcal{W} = \{ \top \rightarrow a \}$ and $\text{SM}[\Gamma_3^\mathcal{W}] = \{ \{ a \} \}$ so $\mathcal{W} = \{ \{ a \} \}$ is a G91-world view. If $\mathcal{W} \models \neg Ka$, the reduct becomes $\Gamma_3^\mathcal{W} = \{ \bot \rightarrow a \}$, a classical tautology with unique stable model $\emptyset$. As a result, $\mathcal{W} = \{ \emptyset \}$ is the second G91-world view of this theory.

2.3 Epistemic Specifications and Epistemic Splitting

In this section, we recall the formal definition of the Epistemic Splitting property. For the motivation of the interest of this property we refer to (Cabalar et al. 2018; Cabalar et al. 2019b).

Let start by introducing a particular class of theories that correspond to the syntax of epistemic specifications or (epistemic logic) programs. Given a set of atoms $S \subseteq At$, by $\neg S \overset{\text{def}}{=} \{ \neg a \mid a \in S \}$ and $\neg\neg S \overset{\text{def}}{=} \{ \neg\neg a \mid a \in S \}$ we respectively denote the set resulting of prepend one or two occurrences of the default negation operator $\neg$ to every atom in $S$. An objective literal is either an atom or a truth constant, that is $a \in At \cup \{ \top, \bot \}$, or the result of prepend one or two default negation, $\neg a$. By $Li_{\text{th}} \overset{\text{def}}{=} At \cup \neg At \cup \neg\neg At \cup \{ \top, \bot, \neg \bot, \neg\neg \bot, \neg\neg\bot \}$ we denote the set of all objective literals. A subjective literal is any expression of the form $Kl, \neg Kl$ or $\neg\neg Kl$ with $l \in Li_{\text{th}}$ any objective literal. A literal is either an objective or subjective literal.

A rule $r$ is an implication of the form:

$$a_1 \lor \cdots \lor a_n \leftarrow L_1 \land \cdots \land L_m$$

with $n \geq 0$ and $m \geq 0$, where each $a_i \in At$ is an atom and each $L_j$ a literal. The left hand disjunction

4 For a simpler description of program transformations, we allow truth constants with their usual meaning.
of (5) is called the rule head and abbreviated as Head(r). When n = 0, it corresponds to ⊥ and r is called a constraint. The right hand side of (5) is called the rule body and abbreviated as Body(r).

As usual, we define Body+(r) and Body−(r) as the conjunction of all positive and negative literals in Body(r), respectively, so that Body(r) = Body+(r) ∧ Body−(r). We further define Bodyobj(r) and Bodysubj(r) as the conjunction of all objective and subjective literals in Body(r), respectively, so that Body(r) = Bodyobj(r) ∧ Bodysubj(r). We also define Bodyi(r) = Bodyx(r) ∩ Bodyy(r) with x ∈ {+, −} and y ∈ {obj, subj}. By abuse of notation, we will also use sometimes Body+, Body−, Bodyobj and Bodysubj as the set of literals occurring in those formulas. When m = 0, the body corresponds to ⊤ and r is called a fact (in this case, the body and the arrow symbol are usually omitted). A rule is called objective if all literals occurring in it are objective. A program Π is a (possibly infinite) set of rules and an objective program is a program where all its rules are objective. We are now ready to recall the epistemic splitting property:

**Definition 3** (Epistemic splitting set). A set of atoms U ⊆ At is said to be an epistemic splitting set of a program Π if for any rule r in Π one of the following conditions hold

(i) Atoms(r) ⊆ U,

(ii) (Atoms(Bodyobj(r) ∪ Head(r))) ∩ U = ∅

We define a splitting of Π as a pair (BU(Π), TU(Π)) satisfying BU(Π) ∩ TU(Π) = ∅, BU(Π) ∪ TU(Π) = Π, all rules in BU(Π) satisfy (i) and all rules in TU(Π) satisfy (ii).

With respect to the original definition of splitting set, we can see that the condition for the top program Atoms(Head(r)) ∩ U = ∅ was replaced by the new condition (ii), which intuitively means that the top program may only refer to atoms U in the bottom through epistemic operators. Another observation is that the definition of BU(Π) and TU(Π) is kept non-deterministic in the sense that some rules can be arbitrarily included in one set or the other. These rules correspond to subjective constraints on atoms in U, since these are the only cases that may satisfy conditions (i) and (ii) simultaneously. Then, the idea is similar as in splitting a regular program: first we compute the world views of the bottom program BU(Π) and for each one we compute the world views of the top program after simplifying in it the subjective literals fixed by the bottom part. Formally, given an epistemic splitting set U for a program Π and belief view W, we define E0(Π, W) ≜ TU(Π)W, that is, we make the subjective reduct of the top with respect to W and signature U.

**Definition 4.** Given a semantics S, a pair (Wb, Wt) is said to be a S-solution of Π with respect to an epistemic splitting set U if Wb is a S-world view of BU(Π) and Wt is a S-world view of E0(Π, W).

Notice that this definition depends on a particular semantics S in the sense that each alternative semantics for epistemic specifications will define its own solutions for a given U and Π. In particular, in this paper, we will consider five instantiations of this Definition 4 with semantics S ∈ {G91, FAEEL, FEEL, EEL, AEEL}. Besides the already mentioned G91, Founded Autoepistemic EEL (FAEEL) and Founded EEL (FEEL) semantics,5 we will also consider the EEL and AEEL semantics from (Fariñas del Cerro et al. 2015).

5 To avoid possible confusions between FAEEL, FEEL, AEEL and EEL, we will sometimes write them as Founded Autoepistemic EEL, Founded EEL, Autoepistemic EEL and EEL respectively, when they occur in the same sentence.
Example 5 (Example 3 continued). Back to our example, let now \( \Pi_4 \) be the program consisting of rules (1)-(2) and (4). Then, we can see that \( U = \{ a, b \} \) is an epistemic splitting set of \( \Pi_4 \) and that it satisfies \( B_U(\Pi_4) = \{ (1) - (2) \} \) and \( T_U(\Pi_4) = \{ (4) \} \). Furthermore, we have already seen that \( B_U(\Pi_4) \) corresponds to the theory \( \Gamma_2 \) which has the following two \( G91 \)-world views: \( \{ [a] \} \) and \( \{ [b] \} \). Then, we can see that \( E_U(\Pi_4, \{ [a] \}) = \{ c \leftarrow \top \} \) has a unique \( G91 \)-world view \( \{ c \} \) and that \( E_U(\Pi_4, \{ [b] \}) = \{ c \leftarrow \bot \} \) has the unique \( G91 \)-world view \( \{ \emptyset \} \). As a result, we have two \( G91 \)-solutions of \( \Pi_4 \) with respect to \( \{ a, b \} \): \( \langle \{ [a] \}, \{ [c] \} \rangle \) and \( \langle \{ [b] \}, \{ \emptyset \} \rangle \). It is also easy to check that \( B_U(\Pi_4) \) has two \( G91 \)-world views, \( \{ [a, c] \} \) and \( \{ [b] \} \) that can be obtained by composing the two above solutions.

In the general case, the world views for the global program are reconstructed by the following operation:

\[
\mathbb{W}_b \sqcup \mathbb{W}_t = \{ I_b \cup I_t \mid I_b \in \mathbb{W}_b \text{ and } I_t \in \mathbb{W}_t \}
\]

(remembers that both the bottom and the top may produce multiple world views, depending on the program and the semantics we choose). For any set of atoms \( U \subseteq \mathcal{A} \) and belief view \( \mathbb{W} \), we also define the restriction of \( \mathbb{W} \) to \( U \) as \( \mathbb{W}_U \overset{\text{def}}{=} \{ I \cap U \mid I \in \mathbb{W} \} \). Furthermore, we also define the complement of a set of atoms as \( \mathcal{U} \overset{\text{def}}{=} \mathcal{A} \setminus U \).

Property 1 (Epistemic splitting). A semantics \( \mathcal{S} \) satisfies epistemic splitting if for any epistemic splitting set \( U \) of any program \( \Pi \): \( \mathbb{W} \) is a \( \mathcal{S} \)-world view of \( \Pi \) if and only if there is a \( \mathcal{S} \)-solution \( \langle \mathbb{W}_b, \mathbb{W}_t \rangle \) of \( \Pi \) with respect to \( \mathcal{U} \) such that \( \mathbb{W} = \mathbb{W}_b \sqcup \mathbb{W}_t \).

Theorem 1. Semantics \( G91 \) satisfies epistemic splitting. Furthermore, if \( \mathbb{W} \) is a \( G91 \)-world view of some program \( \Pi \) with respect to some splitting set \( U \), then \( \langle \mathbb{W}_b, \mathbb{W}_t \rangle \) is a \( G91 \)-solution of \( \Pi \) and it satisfies that \( \mathbb{W} = \mathbb{W}_b \sqcup \mathbb{W}_t \).

2.4 Founded Autoepistemic Equilibrium Logic

We recall now the semantics of Founded Autoepistemic Equilibrium Logic (FAEEL) from (Cabalar et al. 2019a). The basic idea is an elaboration of the belief (or KD45) interpretation \( (\mathbb{W},I) \) already seen but replacing belief sets by HT pairs. Thus, the idea of belief view \( \mathbb{W} \) is extended to a non-empty set of HT-interpretations \( \mathbb{W} = \{ \langle H_1, T_1 \rangle, \ldots, \langle H_n, T_n \rangle \} \) and say that \( \mathbb{W} \) is total when \( H_i = T_i \) for all of them, coinciding with the form of belief views \( \mathbb{W} = \{ T_1, \ldots, T_n \} \) we had so far. Similarly, a belief interpretation is now redefined as \( (\mathbb{W}, \langle H, T \rangle) \), or simply \( (\mathbb{W}, H, T) \), where \( \mathbb{W} \) is a belief view and \( \langle H, T \rangle \) stands for the real world, possibly not in \( \mathbb{W} \). A belief interpretation \( (\mathbb{W}, H, T) \) is called total if both \( (H, T) \) and \( \mathbb{W} \) are total. Next, the satisfaction relation is defined as a combination of modal logic KD45 and HT. A belief interpretation \( I = (\mathbb{W}, H, T) \) satisfies a formula \( \varphi \), written \( I \models \varphi \), iff:

- \( I \not\models \bot \),
- \( I \models a \) iff \( a \in H \), for any atom \( a \in \mathcal{A} \),
- \( I \models \varphi_1 \land \varphi_2 \) iff \( I \models \varphi_1 \) and \( I \models \varphi_2 \),
- \( I \models \varphi_1 \lor \varphi_2 \) iff \( I \models \varphi_1 \) or \( I \models \varphi_2 \),
• $I \models \psi_1 \rightarrow \psi_2$ iff both: (i) $I \not\models \psi_1$; or $I \models \psi_2$; and (ii) $(\mathcal{W}', T) \not\models \psi_1$ or $(\mathcal{W}', T) \models \psi_2$.

where\(^6\) $\mathcal{W}' = \{ T_i | \langle H_i, T_i \rangle \in \mathcal{W} \}$.

• $I \models \Box \psi$ iff $(\mathcal{W}, H, T) \models \psi$ for all $(H, T) \in \mathcal{W}$.

A belief interpretation $(\mathcal{W}, H, T)$ is called a belief model of a theory $\Gamma$ iff $(\mathcal{W}, H, T) \models \phi$ for all HT-interpretation $(H_i, T_i) \in \mathcal{W} \cup \{ (H, T) \}$ and all $\phi \in \Gamma$. Given theories $\Gamma$ and $\Gamma'$, we write $\Gamma \models \Gamma'$ when $(\mathcal{W}, H, T) \models \Gamma$ implies $(\mathcal{W}, H, T) \models \Gamma'$ for all belief interpretations. We write $\Gamma \equiv \Gamma'$ iff $\Gamma \models \Gamma'$ and $\Gamma' \models \Gamma$. Furthermore, when $\Gamma$ or $\Gamma'$ are singletons we may omit the brackets around their unique formula.

Recall that the negation of a formula $\neg \phi$ is defined as an abbreviation for the implication $\phi \rightarrow \bot$. The following result is immediate from the above definition plus the persistence property proved in (Cabalar et al. 2019a) (Proposition 1) and explicitly states the evaluation of negation:

**Proposition 1.** Given a belief interpretation $I = (\mathcal{W}, H, T)$ and a formula $\phi$, it follows that $I \models \neg \phi$ iff $(\mathcal{W}', T) \not\models \phi$.

As recalled in Section 2.1, stable models correspond to a class of HT-models called equilibrium models, that is, total minimal models. Similarly, we define now equilibrium belief models as total minimal belief models with respect to the following order relation:

**Definition 5.** We define the partial order $I' \preceq I$ for belief interpretations $I' = (\mathcal{W}', H', T')$ and $I = (\mathcal{W}, H, T)$ when the following three conditions hold:

(i) $T' = T$ and $H' \subseteq H$,

(ii) for every $(H_i, T_i) \in \mathcal{W}$, there is some $(H_i', T_i') \in \mathcal{W}'$, with $H_i' \subseteq H_i$,

(iii) for every $(H_i', T_i') \in \mathcal{W}'$, there is some $(H_i, T_i) \in \mathcal{W}$, with $H_i' \subseteq H_i$.

As usual, $I' \prec I$ means $I' \preceq I$ and $I' \not\models I$.

**Definition 6.** A total belief interpretation $I = (\mathcal{W}, T)$ is said to be an equilibrium belief model of some theory $\Gamma$ iff $I$ is a belief model of $\Gamma$ and there is no other belief model $I'$ of $\Gamma$ such that $I' \prec I$.

By $\text{EQB}[\Gamma]$ we denote the set of equilibrium belief models of $\Gamma$. As a final step, we impose a fixpoint condition to minimise the agent’s knowledge as follows.

**Definition 7.** A total belief view $\mathcal{W}$ is called an autoepistemic equilibrium model or FAEEL-world view of $\Gamma$ iff:

$$\mathcal{W} = \{ T | (\mathcal{W}, T) \in \text{EQB}[\Gamma] \}$$

**Theorem 2** (Main Theorem in Cabalar et al. 2019a). For any theory $\Gamma$, its FAEEL-world views are exactly its founded\(^7\) G91-world views of $\Gamma$.

---

\(^6\) Note that $\mathcal{W}'$ is a belief view as defined in Section 2.2.

\(^7\) For space reasons we omit here the definition of founded world view and refer the reader to (Cabalar et al. 2019a). Intuitively, a world view is founded if all atoms that are true in all its belief set can be derived without cyclic references. If we omit there founded, we obtain that every FAEEL-world view is also a G91-world view, but not necessarily vice-versa.
3 Founded Epistemic Equilibrium Logic

Founded EEL is similar to Founded Autoepistemic EEL, but without the minimisation of knowledge. Technically, this makes Founded EEL simpler in two distinct ways: (i) it directly uses belief views instead of belief interpretations and, as a result, (ii) it lacks the autoepistemic fixpoint condition (Definition 7). Note that, as mentioned in the introduction Founded EEL can be seen as the combination of the stable model semantics with the modal logic S5, while Founded Autoepistemic EEL would be the combination of the stable model semantics with Moore’s Autoepistemic Logic. In this sense, (i) is a direct consequence of the fact that Moore’s Autoepistemic Logic is defined in terms of modal logic KD45 instead of S5. In its turn, (ii) is a consequence of the fact that S5 is a monotonic logic, and thus Founded EEL do not need the autoepistemic fixpoint condition (Definition 7) that Founded Autoepistemic EEL inherits from Moore’s Autoepistemic Logic.

Formally, a belief view $W$ is called an epistemic model of a theory $\Gamma$, in symbols $W \models \Gamma$ iff $(W, H, T) \in W$ and all $\varphi \in \Gamma$. Given theories $\Gamma$ and $\Gamma'$, we write $\Gamma \models_{\text{defn}} \Gamma'$ if $\Gamma \models \Gamma'$ for all belief interpretations. We write $\Gamma \equiv_{\text{defn}} \Gamma'$ and $\Gamma' \equiv_{\text{defn}} \Gamma$. As above, when $\Gamma$ or $\Gamma'$ are singletons we may omit the brackets around their unique formula.

**Proposition 2** (Persistence). $W \models \varphi$ implies $W' \models \varphi$.

**Proof.** Follows directly from Proposition 1 in (Cabalar et al. 2019a).

The following order relation adapts Definition 5 to the case of belief views.

**Definition 8.** Given belief views $W_1$ and $W_2$, we write $W_1 \preceq W_2$ iff the following two conditions hold:

(i) For every $(H_2, T) \in W_2$, there is some $(H_1, T) \in W_1$, with $H_1 \subseteq H_2$.

(ii) For every $(H_1, T) \in W_1$, there is some $(H_2, T) \in W_2$, with $H_1 \subseteq H_2$.

As usual, we write $W_1 \prec W_2$ iff $W_1 \preceq W_2$ and $W_1 \neq W_2$.

Then, equilibrium epistemic models are defined as usual:

**Definition 9.** A total epistemic model $W$ of a theory $\Gamma$ is said to be an epistemic equilibrium model or FEEL-world view iff there is no other epistemic model $W'$ of $\Gamma$ such that $W' \preceq W$.

The following observation establishes a relation between (equilibrium) belief models and (equilibrium) epistemic models similar to the existent between the standard modal logics KD45 and S5. Recall that belief models correspond to the logical product of HT and KD45 while epistemic models come from the logical product of HT and S5.

**Observation 1.** For any theory $\Gamma$ and belief interpretation $I = (W, H, T)$, the following statements hold:

(i) If $I$ is a belief model of $\Gamma$, then $W$ is a epistemic model of $\Gamma$, and

(ii) If $I$ is an equilibrium belief model of $\Gamma$, then $W$ is a equilibrium epistemic model of $\Gamma$.

From this observation the following relation between autoepistemic equilibrium models and epistemic equilibrium models can be established:

**Theorem 3.** Every FAEEL-world view of any theory $\Gamma$ is also an FEEL-world view of $\Gamma$. 

In general the converse does not necessarily hold as illustrated by the following example:

**Example 6.** Consider the program $\Pi_1$ consisting of the single rule $a \lor b$. This program has two stable models, $\{a\}$ and $\{b\}$ and accordingly a unique FAEEL-world view $\{\{a\}, \{b\}\}$ which agrees with its unique G91-world view. On the other hand, this program has two extra FEEL-world views that are not FAEEL-world views: $\{\{a\}\}$ and $\{\{b\}\}$. These two extra models are clearly not well-justified in an epistemic sense as they respectively satisfy $K_a$ and $K_b$ with no evidence for that conclusion. Finally, to see the difference between FEEL and modal logic S5, note that $\{\{a, b\}\}$ is also an S5 model which is neither a FEEL nor a FAEEL-world view.

This example also illustrates that the difference between FAEEL and FEEL can be formalised in terms of the supra-ASP property introduced in (Cabalar et al. 2019b) and recalled below: FAEEL satisfies supra-ASP (Cabalar et al. 2019a, Proposition 3) while FEEL does not.

**Property 2 (Supra-ASP).** A semantics $S$ satisfies supra-ASP if for any objective program $\Pi$ either $\Pi$ has a unique $S$-world view $W = SM[\Pi] \neq \emptyset$ or both $SM[\Pi] = \emptyset$ and $\Pi$ has no $S$-world view at all.

On the other hand, the following result shows that we can obtain FAEEL-world views as the intersection of FEEL and G91-world views:

**Theorem 4.** For any theory $\Gamma$, a belief view $W$ is a FAEEL-world view iff (i) $W$ is a FEEL-world view and (ii) $W$ is a G91-world view.

**Example 7 (Example 4 continued).** Back to $\Gamma_3 = \{K a \rightarrow a\}$, recall that this theory has two G91-world views: $\emptyset$ and $\{a\}$. It is easy to see that $\emptyset$ is a FEEL-world view and, from Theorem 4, this implies that this is also a FAEEL-world view. Note that there is no smaller belief view than $\emptyset$, so being a model is enough to show that is a FEEL-world view. Note that, by using Theorem 4, is much easier to see that $\emptyset$ is a FEEL-world view than directly applying their definition because belief views are simpler than belief interpretations and because the autoepistemic fixpoint can be checked independently using the G91-semantics.

4 Epistemic Splitting in Founded (Auto)Epistemic Equilibrium Logic

Let us now study the epistemic splitting property in FEEL and FAEEL. Let us start by stating a result analogous to Theorem 1, but this time for FEEL.

**Theorem 5 (Epistemic splitting in FEEL).** FEEL satisfies the epistemic splitting property. Furthermore, if $W$ is a FEEL-world view of some program $\Pi$ with respect to some splitting set $U$ then $(W_U, W_{\overline{U}})$ is a FEEL-solution of $\Pi$ and it satisfies that $W = W_U \cup W_{\overline{U}}$.
The proof of Theorem 5 is based in the following auxiliary results whose proof can be found in the supplementary material.

**Proposition 3.** Let $U \subseteq \text{At}$ be some set of atoms and $\Pi = \Pi_1 \cup \Pi_2$ be a program such that $\text{Atoms}(\Pi_1) \subseteq U$ and $\text{Atoms}(\Pi_2) \subseteq U$. Then, any belief view $W$ is an FEEL-world view of $\Pi$ iff $W_{\Pi_U}$ is an FEEL-world view of $\Pi_1$ and $W_{\Pi_U}$ is an FEEL-world view of $\Pi_2$. \hfill $\square$

Intuitively, Proposition 3 says that, if we can split a program in a way that its two halves do not share atoms in common, then we can compute the world views of the whole program by combining the world views of each half. Furthermore, the following result shows that we can check whether a belief view is an FEEL-world view by checking instead that that belief view is a FEEL-world view of a program obtained by simplifying the subjective literals in the rules of the top part accordingly to the belief view.

**Proposition 4.** Let $\Pi$ be a program obtained with epistemic splitting set $U \subseteq \text{At}$. Then, any belief view $W$ is an FEEL-world view of $\Pi$ iff $W$ is an FEEL-world view of $B_U(\Pi)$ and $W_{\Pi_U}$ is an FEEL-world view of $E_U(\Pi, W_U)$. \hfill $\square$

We can now join Propositions 3 and 4 to show the following rewriting of epistemic splitting.

**Proposition 5.** Given any program $\Pi$ and epistemic splitting set $U$ of $\Pi$, a belief view $W$ is an FEEL-world view of $\Pi$ iff $W_{\Pi_U}$ is an FEEL-world view of $B_U(\Pi)$ and $W_{\Pi_U}$ is an FEEL-world view of $W_{\Pi_U}$ of $E_U(\Pi, W_U)$. \hfill $\square$

**Proof.** First note that, from Proposition 4, it follows that $W$ is an FEEL-world view of $\Pi$ iff $W$ is an FEEL-world view of $B_U(\Pi) \cup E_U(\Pi, W)$. Furthermore, we have $E_U(\Pi, W) = E_U(\Pi, W_{\Pi_U})$. Therefore, we immediately can see that $W$ is an FEEL-world view of $\Pi$ iff $W$ is an FEEL-world view of $B_U(\Pi) \cup E_U(\Pi, W_{\Pi_U})$. Furthermore, by construction we have $\text{Atoms}(B_U(\Pi)) \subseteq U$ and $\text{Atoms}(E_U(\Pi, W_{\Pi_U})) \subseteq U$ and, from Proposition 3, this implies that the latter holds iff $W_{\Pi_U}$ is an FEEL-world view of $B_U(\Pi)$ and $W_{\Pi_U}$ is an FEEL-world view of $E_U(\Pi, W_U)$. \hfill $\square$

**Proof of Theorem 5.** Assume first that $W$ is an equilibrium epistemic model of $\Pi$. Then, from Proposition 5, it follows that $W_{\Pi_U}$ is an FEEL-world view of $B_U(\Pi)$ and $W_{\Pi_U}$ is an FEEL-world view of $W_{\Pi_U}$ of $E_U(\Pi, W_{\Pi_U})$ and it is easy to check that $W = W_{\Pi_U} \cup W_{\Pi_U}$. The other way around, assume there are FEEL-world views $W_b$ of $B_U(\Pi)$ and $W_t$ of $E_U(\Pi, W_{\Pi_U})$, and let $W = W_b \cup W_t$. Note that $\text{Atoms}(B_U(\Pi)) \subseteq U$ implies that every interpretation $T \in W_b$ satisfies $T \subseteq U$ and that $\text{Atoms}(E_U(\Pi, W_{\Pi_U})) \subseteq U$ implies that every $T \in W_t$ satisfies $T \subseteq U$. Hence, it follows that $W_{\Pi_U} = W_b$ and $W_{\Pi_U} = W_{\Pi_U}$ and the result follows directly from Proposition 5. \hfill $\square$

We can now use Theorem 5 in combination with Theorems 1 and 4 to show that FAEEEL also satisfies epistemic splitting.

**Main Theorem (Epistemic splitting in FAEEEL).** FAEEEL satisfies the epistemic splitting property. Furthermore, if $W$ is a FAEEEL-world view of some program $\Pi$ with respect to some splitting set $U$ then $(W_b, W_t)$ is a FAEEEL-solution of $\Pi$ and it satisfies $W = W_{\Pi_U} \cup W_{\Pi_U}$. \hfill $\square$

**Proof.** Assume first that there is FAEEEL-solution $(W_b, W_t)$ of some program $\Pi$ with respect to some splitting set $U$ and let $W = W_b \cup W_t$. By definition, this implies that $W_b$ is a FAEEEL-world view of $B_U(\Pi)$ which, from Theorem 4, implies that $W_b$ is both a FEEL and a G91-world view of $B_U(\Pi)$. Similarly, we can see that $W_t$ is both a FEEL and a G91-world view of $E_U(\Pi, W_{\Pi_U})$ and, thus, that $(W_b, W_t)$ is both a FEEL and a G91-solution of $\Pi$ with respect $U$. From Theorems 1
and 5, these two facts respectively imply that $\mathcal{W}$ is both a FEEL and a G91-world view of $\Pi$ which, from Theorem 4 again, implies that $\mathcal{W}$ is a FAEELE-world view of $\Pi$.

The other way around is analogous. Assume now that $\mathcal{W}$ is a FAEELE-world view of some program $\Pi$ with splitting set $U$. Then, from Theorem 4, it follows that $\mathcal{W}$ is both a FEEL and a G91-world view. From Theorems 1 and 5, these two facts respectively imply that $(\mathcal{W}_U, \mathcal{W}_T)$ is a FEEL and a G91-solution of $\Pi$ with respect to $U$ and $\mathcal{W} = \mathcal{W}_U \cup \mathcal{W}_T$. Finally, from Theorem 4 again, this implies that $(\mathcal{W}_U', \mathcal{W}_T')$ is also a FAEELE-solution.

It is interesting to note that for any semantics that satisfies epistemic splitting, thus FAEELE and G91, constraints indented to remove world views are well-behaved:

**Property 3** (Subjective constraint monotonicity). A semantics satisfies subjective constraint monotonicity if, for any epistemic program $\Pi$ and any subjective constraint $r$, $W$ is a world view of $\Pi \cup \{ r \}$ iff both $W$ is a world view of $\Pi$ and $W \models r$.

**Theorem 6** (Theorem 2 in Cabalar et al. 2019b). 

**Epistemic splitting implies subjective constraint monotonicity.**

Furthermore, this property also guarantees that, for epistemically stratified programs, these semantics have at most a unique world view (see Theorem 1 in Cabalar et al. 2019b). Another interesting property, not included in (Cabalar et al. 2019b), is that any semantics that satisfies epistemic splitting and the supra-ASP property, necessary coincides with the G91-semantics for the class of epistemic stratified programs. Before tackling the notion of epistemic stratification, let us recall the epistemic dependence relation among atoms in a program $\Pi$ so that $\text{dep}(a, b)$ is true iff there is a rule $r \in \Pi$ such that $a \in \text{Atoms}(\text{Head}(r) \cup \text{Body}_{\text{obj}}(r))$ and $b \in \text{Atoms}(\text{Body}_{\text{sub}}(r))$.

**Definition 10.** We say that an epistemic program $\Pi$ is epistemically stratified if we can assign an integer mapping $\lambda : \text{Atoms} \rightarrow \mathbb{N}$ to each atom such that

(i) $\lambda(a) = \lambda(b)$ for any rule $r \in \Pi$ and atoms $a, b \in (\text{Atoms}(r) \setminus \text{Body}_{\text{sub}}(r))$.
(ii) $\lambda(a) > \lambda(b)$ for any pair of atoms $a, b$ satisfying $\text{dep}(a, b)$.

**Theorem 7.** Given any two semantics $S$ and $S'$ that satisfy the epistemic splitting and supra-ASP properties and an epistemically stratified program $\Pi$, one of following two condition hold:

(i) $\Pi$ has neither $S$-world view nor $S'$-world view, or
(ii) $\Pi$ has exactly one $S$ and one $S'$-world view $\mathcal{W}$ which is the same in both semantics.

**Proof.** The proof follows by induction in the number of layers induced by the stratifications. Note that, if a program has a unique layer, then it must be objective and, thus, the result follows directly from the supra-ASP property. Otherwise, let $a \in At$ such that there is no $b \in At$ with $\lambda(a) < \lambda(b)$ and let $U = \{ c \in At \mid \lambda(c) < \lambda(a) \}$. Then, $U$ is an splitting set of $\Pi$ and the epistemic splitting property tell us a belief view $\mathcal{W}$ is a $S$-world view of $\Pi$ iff there are $S$-world views $\mathcal{W}_b$ of $B_U(\Pi)$ and $\mathcal{W}_t$ of $E_U(\Pi, \mathcal{W}_b)$. Furthermore, $B_U(\Pi)$ and $E_U(\Pi, \mathcal{W}_b)$ have less layers than $\Pi$ so, by induction hypothesis, this holds iff there are $S'$-world views $\mathcal{W}_b$ of $B_U(\Pi)$ and $\mathcal{W}_t$ of $E_U(\Pi, \mathcal{W}_b)$ iff $\mathcal{W}$ is a $S'$-world view of $\Pi$.

**Corollary 1.** For epistemically stratified programs, FAEELE and G91-world views coincide.

Note that Corollary 1 does not apply to FEEL because this semantics does not satisfy supra-ASP as illustrated by Example 6. Recall also that, from Proposition 2 in (Cabalar et al. 2019a), we
already knew that, for programs where all occurrences of $K$ are in the scope of negation, FAEEL and G91-world views coincide. Corollary 1 enlarges the class programs in which FAEEL and G91 coincide by including all those that are epistemically stratified. This immediately arises the question whether FAEEL and G91 also coincide for programs without positive cycles involving epistemic literals. The following result shows that this is indeed the case. Formally, we define the positive epistemic dependence relation among atoms in a program $\Pi$ so that $\text{dep}^+(a, b)$ is true iff there is a rule $r \in \Pi$ such that $a \in \text{Atoms}(\text{Head}(r) \cup \text{Body}_{\text{obj}}(r))$ and $b \in \text{Atoms}(\text{Body}_{\text{sub}}(r))$.

**Definition 11** (Epistemically tight program). We say that an epistemic program $\Pi$ is epistemically tight if we can assign an integer mapping $\lambda : \text{At} \to \mathbb{N}$ to each atom such that

(i) $\lambda(a) = \lambda(b)$ for any rule $r \in \Pi$ and atoms $a, b \in (\text{Atoms}(r) \setminus \text{Body}_{\text{sub}}(r))$,

(ii) $\lambda(a) > \lambda(b)$ for any pair of atoms $a, b$ satisfying $\text{dep}^+(a, b)$. □

**Definition 12.** Given an epistemic theory $\Gamma$ and a belief view $\mathbb{W}$, its negatively subjective reduct, in symbols $\Gamma^{\mathbb{W}}$, is obtained by replacing each maximal subjective formula of the form $\neg K \varphi$ by $\top$ if $\mathbb{W} \not\models K \varphi$; or by $\bot$ otherwise. □

**Proposition 6.** Given a theory $\Gamma$ and, a total belief view $\mathbb{W}$ is FAEEL-world view of $\Gamma$ iff $\mathbb{W}$ is a FAEEL-world view of $\Gamma^{\mathbb{W}}$.

**Theorem 8.** For epistemically tight programs, FAEEL and G91-world views coincide. □

**Proof.** For any belief view $\mathbb{W}$ and epistemically tight program $\Pi$ it follows that $\mathbb{W}$ is FAEEL-world view of $\Pi$ iff $\mathbb{W}$ is a FAEEL-world view of $\Pi^{\mathbb{W}}$ (Proposition 6). Furthermore, it is easy to see that, since $\Pi$ is epistemically tight, $\Pi^{\mathbb{W}}$ is also epistemically tight. Moreover, for every $r \in \Pi^{\mathbb{W}}$ and every $L \in \text{Body}_{\text{sub}}(r)$, we can check that $L \in \text{Body}^{\top}(r)$. That is, there are no subjective literals in the scope of negation and, thus, $\Pi^{\mathbb{W}}$ being epistemically tight implies that $\Pi^{\mathbb{W}}$ is epistemically stratified. Then, the result follows directly from Corollary 1. □

It is also worth to mention that, as observed in (Cabalar et al. 2019a), it is possible to obtain Moore’s Autoepistemic Logic from FAEEL simply by adding the exclude middle axiom $p \lor \neg p$ for every atom in the signature. Note that, if the original program was stratified, augmenting it with these formulas does not change this property. As a result we obtain the following corollary:

**Corollary 2.** Any epistemically stratified program $\Pi$ has at most one Moore’s autoepistemic extension. □

A similar result was originally proved in (Gelfond 1987, Theorem 4). Note that the class of programs considered stratified by us is slightly broader than the one used in (Gelfond 1987): constraints are allowed in every strata and no distinction is made between positive and negative objective literals. The price to pay is that Corollary 2 does not ensure the existence of an extension.

## 5 Related work

As mentioned in the introduction, the search for a “satisfactory” semantics for epistemic logic programs has leave us with a variety of semantics (Gelfond 1991; Wang and Zhang 2005; Truszczynski 2011; Gelfond 2011; Fariñas del Cerro et al. 2015; Kahl et al. 2015; Shen and Eiter 2017; Cabalar et al. 2019a). Among this Epistemic Equilibrium Logic (EEL; Fariñas del Cerro...
et al. 2015) is very similar to Founded EEL in the sense that it is also defined as a combination of Equilibrium Logic and the modal logic S5. There are some slight differences though, and as the name suggest Founded EEL satisfies the founded property defined (Cabalar et al. 2019a) while EEL does not. In fact, EEL can be characterised by a particular class of belief views that we call here simple:

**Definition 13.** We say that a belief view \( \mathcal{W} \) is simple iff for any \( \langle H, T \rangle \in \mathcal{W} \) and \( \langle H', T' \rangle \in \mathcal{W} \), we have \( H = H' \). A a total belief view \( \mathcal{W} \) is called an EEL-world view of a theory \( \Gamma \) iff \( \mathcal{W} \) is a belief model of \( \Gamma \) and there is no simple belief model \( \mathcal{W}' \) of \( \Gamma \) satisfying \( \mathcal{W} = (\mathcal{W}')' \) and \( H \subset T \) for some \( \langle H, T \rangle \in \mathcal{W}' \).

It is easy to see that Definition 13 is just a rephrasing of epistemic equilibrium models as defined in (Fariñas del Cerro et al. 2015) by using the notation of this paper.

**Proposition 7.** A a total belief view \( \mathcal{W} \) is an EEL-model of a theory \( \Gamma \) iff \( \mathcal{W} \) is a belief model of \( \Gamma \) and there is no simple belief model \( \mathcal{W}' \) of \( \Gamma \) such that \( \mathcal{W}' \prec \mathcal{W} \).

**Theorem 9.** Every FAEEL and FEEL-world view of any theory \( \Gamma \) is also an EEL-world view.

**Proof.** Note that that every total belief view is simple, though there are non-total belief views that are not simple. Then, the result follows directly from Proposition 7 and Theorem 3.

As illustrated by the following example, in general, the converse of Theorem 9 does not hold.

**Example 8.** Take the epistemic logic program:

\[
\begin{align*}
  a \lor b & \quad a \leftarrow K b \\
  b & \leftarrow K a
\end{align*}
\] (\( \Pi_2 \))

whose unique epistemic equilibrium model is \( \mathcal{W} = \langle \{a\}, \{b\} \rangle \). Note that \( \mathcal{W}' = \langle \{a, b\} \rangle \) is not an epistemic equilibrium model because \( \mathcal{W}' \prec \mathcal{W} \) with \( \mathcal{W}'' = \langle \{a\}, \{a, b\} \rangle, \langle \{b\}, \{a\} \rangle \rangle \). However, \( \mathcal{W} \) is an EEL-model. Note that \( \mathcal{W}'' \) is not a simple belief view and, thus, cannot be used as a witness to show that \( \mathcal{W}' \) is not an EEL-model. On the other hand, the simple belief views \( \langle \{a\}, \{a, b\} \rangle \), \( \langle \{b\}, \{a\} \rangle \), and \( \langle \emptyset, \{a, b\} \rangle \rangle \) are not models of this program.

Interestingly, it can be shown that EEL also satisfies epistemic splitting.

**Theorem 10** (Epistemic splitting in EEL). EEL satisfies the epistemic splitting property. Furthermore, if \( \mathcal{W} \) is a EEL-world view of some program \( \Pi \) with respect to some splitting set \( U \) then \( \langle \mathcal{W}_U, \mathcal{W}_G \rangle \) is a EEL-solution of \( \Pi \) and it satisfies that \( \mathcal{W} = \mathcal{W}_U \cup \mathcal{W}_G \).

The proof of Theorem 10 is analogous to the proof of Theorem 5 just taking into account that now we have to restrict ourselves to simple interpretations. Note that, in general, EEL does not satisfy supra-ASP. Example 6 can be used to illustrate this statement and, in fact, the program in this example has exactly the same EEL-world views as FEEL-world views. For this reason (Fariñas del Cerro et al. 2015) also included a selection of EEL-world views called AEEL-world views in a similar spirit as how FAEEL-world views are a selection of FEEL-world views. However, it has been shown in (Cabalar et al. 2018; Cabalar et al. 2019b) that AEEL does not satisfy epistemic splitting. Theorem 10 sheds more light into this issue by showing that it is not the EEL logic, but the selection of AEEL-world views, what breaks the splitting property. In this sense, it would be possible to define AEEL-world views in an alternative way as the intersection of EEL-world views and G91-world views and obtain yet another semantics that satisfy epistemic splitting. Note though that this alternative semantics (EEL+G91) would not satisfy the...

Founded (Auto)Epistemic Equilibrium Logic Satisfies Epistemic Splitting

foundedness property introduced in (Cabalar et al. 2019a). In fact, a variation of Example 8, obtained by adding the constraint ⊥ ← ¬Ka to program Π2, was used (Cabalar et al. 2019a) to show that, among others, AEEL does not satisfy the foundedness property. This same example can also be used to show that EEL and EEL+G91 do not satisfy it.

To summarise the state of the art, let us recall the remaining property introduced in (Cabalar et al. 2018; Cabalar et al. 2019b):

**Property 4 (Supra-S5).** A semantics satisfies supra-S5 when for every world view W of an epistemic program Π and for every I ∈ W, ⟨W, I⟩ |= Π.

Table 1 summarises the known results for different semantics with respect to Properties 1-4 plus foundedness. Recall that, intuitively, foundedness means that a semantics is free of self-supported world view. For space reasons, we refer to (Cabalar et al. 2019a) for a formal definition. Recall also that (Wang and Zhang 2005; Truszczyński 2011) extended the semantics of G91 to arbitrary theories in different ways, but for the class of logic programs both of them agree with G91. For this reason, we will refer to both of them just as G91 in the table. Counterexamples for the non satisfied properties can be found in (Kahl and Leclerc 2018; Cabalar et al. 2018; Cabalar et al. 2019b; Cabalar et al. 2019a) and in this paper for the case of EEL and FEEL not satisfying Supra-ASP. Proofs for the satisfied properties can be found in (Cabalar et al. 2018; Cabalar et al. 2019b; Cabalar et al. 2019a) and in this paper. To complete the table, the following result shows that, despite not satisfying epistemic splitting, the semantics proposed by Gelfond (2011) does satisfy subjective constraint monotonicity.

**Proposition 8.** The semantics defined by Gelfond (2011) satisfies subjective constraint monotonicity.

6 Conclusions

We have shown that Founded Autoepistemic EEL satisfies the epistemic splitting, a desirable property for epistemic logic programs that, among previous semantics, was known to be satisfied only by G91. On the other hand, it is well-known that the G91 semantics suffers from self-supported world views, something that was proved to be not the case for Founded Autoepistemic EEL in (Cabalar et al. 2019a). In this sense, Founded Autoepistemic EEL is the first semantics whose world views are not self-supported and that satisfies epistemic splitting. Furthermore,
we have shown that, for epistemic tight programs (those not containing cycles involving positive epistemic literals), both G91 and Founded Autoepistemic EEL coincide. This means that Founded Autoepistemic EEL corrects the problem with self-supported world views present in G91 without introducing further variations that are unrelated to this problem.

In addition, we have introduced Founded EEL, a logic which can be considered as a combination of the stable models semantics and the modal logic S5, and an alternative characterisation of Founded Autoepistemic EEL-world views in terms of Founded EEL and G91. This alternative characterisation may help us to further study properties of Founded Autoepistemic EEL and, in fact, it already has been used to prove the epistemic splitting property, strengthen the relation between Founded Autoepistemic EEL and G91, and also to study the relation with the Epistemic Equilibrium Logic introduced by Fariñas del Cerro et al. (2015).

Appendix A Proofs of Results

The proof of Theorem 4 rely on the definition of weak autoepistemic world views which coincide with G91-world views. Let us start by defining semi-total interpretations. We say that an interpretation \( \langle \mathbb{W}, H, T \rangle \) is belief-total iff \( \mathbb{W} \) is total. It is easy to see that, every total interpretation is belief-total but not vice-versa.

Definition 14. A total interpretation \( \mathcal{I} \) is said to be a weak equilibrium model of some theory \( \Gamma \) iff \( \mathcal{I} \) is a model of \( \Gamma \) and there is no other belief-total model \( \mathcal{I}' \) of \( \Gamma \) such that \( \mathcal{I}' \prec \mathcal{I} \).

Note that every equilibrium model is also a weak equilibrium model, but not vice-versa. For instance, \( ([\{a\}], \{a\}) \) is a weak equilibrium model of \( \{a \leftarrow \text{K}a\} \) but not a equilibrium model. By WEQB[\( \Gamma \)] we denote the set the weak equilibrium belief models of \( \Gamma \). As in FAEEL, we impose a fixpoint condition to minimise the agent’s knowledge as follows.

Definition 15. A total belief view \( \mathbb{W} \) is called a weak autoepistemic world view of \( \Gamma \) iff
\[
\mathbb{W} = \{ T \mid (\mathbb{W}, T) \in \text{WEQB}[\Gamma] \}
\]

Lemma 1. Let \( \Gamma \) be a formula and \( \mathcal{I} = \langle \mathbb{W}, H, T \rangle \) be a semi-total interpretation. Then, \( \mathcal{I} \) is a model of \( \varphi \) iff \( \mathcal{I} \) is a model of \( \varphi^\mathbb{W} \).

Proof. Assume that \( \varphi = \text{K} \psi \). Then, we have that \( \langle \mathbb{W}, H', T' \rangle \models \varphi \) if and only if \( \langle \mathbb{W}, T', T'' \rangle \models \psi \) for every \( \langle T'', T'' \rangle \in \mathbb{W} \) iff \( \mathbb{W} \) is a SS-model of \( \varphi \) iff \( \varphi^\mathbb{W} = \top \) iff \( \mathcal{I} \models \varphi^\mathbb{W} \). Then, by induction in the structure of \( \varphi \), we get that \( \mathcal{I} \models \varphi \) iff \( \mathcal{I} \models \varphi^\mathbb{W} \). Finally, we have that \( \mathcal{I} \models \varphi \) iff \( \mathcal{I} \models \varphi^\mathbb{W} \).

Lemma 2. Let \( \Gamma \) be a propositional theory and \( \mathcal{I} = \langle \mathbb{W}, H, T \rangle \) be some interpretation. Then, \( \mathcal{I} \) is a model of \( \Gamma \) iff \( \langle H', T' \rangle \) is a HT-model of \( \Gamma \) for every HT-interpretation \( \langle H', T' \rangle \in \mathbb{W} \cup \{\langle H, T \rangle\} \).

Theorem 11. Given a theory \( \Gamma \) and some belief view \( \mathbb{W} \), we have that \( \mathbb{W} \) is a weak autoepistemic world view of \( \Gamma \) iff \( \mathbb{W} \) is a G91-world view of \( \Gamma \).

Proof. From Lemmas 1 and 2, we have that \( \langle \mathbb{W}, T \rangle \in \text{WEQ}[\Gamma] \) iff \( \langle \mathbb{W}, T \rangle \in \text{WEQ}[\Gamma^\mathbb{W}] \) iff \( \mathbb{W} \cup \{T\} \subseteq \text{SM}[\Gamma^\mathbb{W}] \) and, therefore, Definition 15 can be rewriting as
\[
\mathbb{W} = \{ T \mid \mathbb{W} \cup \{T\} \subseteq \text{SM}[\Gamma^\mathbb{W}] \}
\]
iff \( \mathbb{W} = \{ T \mid T \in \text{SM}[\Gamma^\mathbb{W}] \} \) iff \( \mathbb{W} = \text{SM}[\Gamma^\mathbb{W}] \) iff \( \mathbb{W} \) is a G91-world view of \( \Gamma \).

Proposition 9. Every FAEEEL-world view is also a weak autoepistemic world view.

Proof. Since every equilibrium model is also a weak equilibrium model, it only remains to be shown that if \( \mathbb{W} \) is an autoepistemic world view then there not exists any propositional interpretation \( T \) such that \( \langle \mathbb{W}, T \rangle \) is a weak equilibrium model of \( \Gamma \) and \( T \notin \mathbb{W} \).
Suppose, for the sake of contradiction, that there is some propositional interpretation \( T \) such that \( \langle \mathcal{W}, T \rangle \) is a weak equilibrium model of \( \Gamma \) and \( T \notin \mathcal{W} \). Since \( \mathcal{W} \) is an autoepistemic world view, this implies that \( \langle \mathcal{W}, T \rangle \) is not an equilibrium model of \( \Gamma \) and, thus, that there is some semi-total model \( \mathcal{T}' = \langle \mathcal{W}', H, T \rangle \) of \( \Gamma \) such that \( \mathcal{T}' \prec \mathcal{T} \). Hence, there is some \( \langle H', T' \rangle \in \mathcal{W}' \) such that \( H' \subset T' \). Let \( \mathcal{T}'' = \langle \mathcal{W}', H', T' \rangle \). Then, we have that \( \mathcal{T}'' \prec \langle \mathcal{W}, T' \rangle \) and, since \( \mathcal{W} \) is an autoepistemic world view of \( \Gamma \) and \( T \in \mathcal{W} \), we have that \( \langle \mathcal{W}, T' \rangle \) is an equilibrium model of \( \Gamma \). These two facts together imply that \( \mathcal{T}'' \) is not a model of \( \Gamma \). Hence, there is a formula \( \phi \in \Gamma \) such that \( \mathcal{T}'' \) is not a model of \( \phi \) and, thus, there is \( \langle H'', T'' \rangle \in \mathcal{W}' \cup \{ \langle H', T' \rangle \} \) such that \( \langle \mathcal{W}', H'', T'' \rangle \neq \phi \). On the other hand, since \( \mathcal{T}' \) is a model of \( \Gamma \), it follows that \( \langle \mathcal{W}', H'', T'' \rangle \neq \phi \) for every \( \langle H'', T'' \rangle \in \mathcal{W}' \cup \{ \langle H, T \rangle \} \). Hence, it follows that \( H'' = H' \) and \( T'' = T' \) and that \( \langle \mathcal{W}', H', T' \rangle \neq \phi \). However, since \( \langle H', T' \rangle \in \mathcal{W}' \), this implies that \( \mathcal{T}' = \langle \mathcal{W}', H, T \rangle \neq \phi \), which is a contradiction with the fact that \( \mathcal{T}' \) is a model of \( \Gamma \). Consequently, \( \mathcal{W} \) is a weak autoepistemic world view.

**Lemma 3.** Let \( \Gamma \) be a theory, \( \mathcal{W} \) be an FEEL-world view of \( \Gamma \) and \( T \in \mathcal{W} \) be a propositional interpretation. If \( \langle \mathcal{W}, T \rangle \) is a weak equilibrium belief model of \( \Gamma \), then \( \langle \mathcal{W}, T \rangle \) is also an equilibrium belief model of \( \Gamma \).

**Proof.** Suppose that \( \langle \mathcal{W}, T \rangle \) is not an equilibrium model of \( \Gamma \). Since \( \langle \mathcal{W}, T \rangle \) is a weak equilibrium model of \( \Gamma \), we have that \( \langle \mathcal{W}, T \rangle \) is a belief model of \( \Gamma \) and, thus, there must be some non-semi-total model \( \mathcal{T}' = \langle \mathcal{W}', H, T \rangle \) of \( \Gamma \) such that \( \mathcal{T}' \prec \mathcal{T} \). Hence, there is \( \langle H', T' \rangle \in \mathcal{W}' \) with \( H \subset T \). This implies that \( \mathcal{W}' \prec \mathcal{W} \) and, since \( \mathcal{W} \) is an FEEL-world view of \( \Gamma \), \( \mathcal{W} \) is not an epistemic model of \( \Gamma \). Hence, \( \mathcal{W}' \) is not an epistemic model of \( \Gamma \) either. This implies that there is some formula \( \phi \in \Gamma \) and HT-interpretation \( \langle H'', T'' \rangle \in \mathcal{W}' \) such that \( \langle \mathcal{W}', H'', T'' \rangle \neq \phi \). In its turn, this implies that \( \mathcal{T}' \) is not belief model of \( \Gamma \) which is a contradiction. Consequently, \( \langle \mathcal{W}, T \rangle \) is an equilibrium belief model of \( \Gamma \).

**Proof of Theorem 4.** First note that from Proposition 3 and 9, it follows that every FAEEL-world view is both an FEEL-world view and a weak autoepistemic world view of \( \Gamma \). The other way around. Since \( \mathcal{W} \) is a weak autoepistemic equilibrium model of \( \Gamma \), it follows that \( \langle \mathcal{W}, T \rangle \) is a weak equilibrium model of \( \Gamma \) for every \( T \in \mathcal{W} \), which, from Lemma 3, implies that \( \langle \mathcal{W}, T \rangle \) is an equilibrium belief model of \( \Gamma \) for every \( T \in \mathcal{W} \). Hence, it only remains to be shown that the following condition hold:

there is no propositional interpretation \( T \) such that model \( \langle \mathcal{W}, T \rangle \) is an equilibrium belief model of \( \Gamma \) and \( T \notin \mathcal{W} \).

Suppose, for the sake of contradiction, that there is some propositional interpretation \( T \) such that model \( \langle \mathcal{W}, T \rangle \) is an equilibrium belief model of \( \Gamma \) and \( T \notin \mathcal{W} \). First, this implies that \( \langle \mathcal{W}, T \rangle \) is an belief model of \( \Gamma \). Then, since \( \mathcal{W} \) is a weak autoepistemic equilibrium model of \( \Gamma \) and \( T \notin \mathcal{W} \), it follows that \( \langle \mathcal{W}, T \rangle \) cannot be a weak autoepistemic equilibrium model of \( \Gamma \) and, thus, there is some semi-total belief model \( \mathcal{J} \) of \( \Gamma \) such that \( \mathcal{J} \prec \langle \mathcal{W}, T \rangle \). But every semi-total belief model is also a belief model, so this is a contradiction with the fact that \( \langle \mathcal{W}, T \rangle \) is an equilibrium belief model of \( \Gamma \). Consequently, \( \mathcal{W} \) must be an autoepistemic world view of \( \Gamma \).

**Proposition 10** (Free atom invariance). Given a set of atoms \( U \subseteq \text{At} \), a formula \( \phi \) such that \( \text{Atoms}(\phi) \subseteq U \) and a pair of belief views \( \mathcal{W} \) and \( \mathcal{W}' \) such that \( \mathcal{W} |_U = \mathcal{W}' |_U \), it follows that \( \mathcal{W} \models \phi \iff \mathcal{W}' \models \phi \).

\[ \square \]
Proof. By definition, it follows that \( \mathcal{W} \models \phi \) iff \((\mathcal{W}, H_i, T_i) \models \phi \) for all \( \langle H, T_i \rangle \in \mathcal{W} \) and that \( \mathcal{W}' \models \phi \) iff \((\mathcal{W}', H_i, T_i) \models \phi \) for all \( \langle H, T_i \rangle \in \mathcal{W}' \). Then, if \( \phi \in \text{At} \) is an atom, we have \( \phi \in U \) and, thus, it follows that \( \mathcal{W} \models \phi \) iff \((\mathcal{W}, H_i, T_i) \models \phi \) for all \( \langle H, T_i \rangle \in \mathcal{W} \) iff \( a \in H_i \) for all \( \langle H, T_i \rangle \in \mathcal{W} \) iff \( a \in H' \) for all \( \langle H', T_i \rangle \in \mathcal{W}' \) iff \( \mathcal{W}' \models \phi \). The rest of the proof follows by induction in the structure of the formula.

Let us now extended the operation \( \sqcup \) to possibly non-total belief views as follows:

\[
\mathcal{W}_b \sqcup \mathcal{W}_t = \{ \langle H_b \cup H_t, T_b \cup T_t \rangle : \langle H_b, T_b \rangle \in \mathcal{W}_b \text{ and } \langle H_t, T_t \rangle \in \mathcal{W}_t \}
\]

**Lemma 4.** Let \( U \subseteq \text{At} \) be some set of atoms and let \( \mathcal{W} \) and \( \mathcal{W}_1 \) be two belief views such that \( \mathcal{W} \preceq \mathcal{W}_1 \). Then, \( \mathcal{W}_1 \sqcup \mathcal{W}_\mathcal{T} \preceq \mathcal{W} \).

*Proof.* Let \( \mathcal{W}' = \mathcal{W}_1 \sqcup \mathcal{W}_\mathcal{T} \) and suppose, for the sake of contradiction, \( \mathcal{W}' \not\preceq \mathcal{W} \). Then

1. There is \( \langle H, T \rangle \in \mathcal{W} \) such that \( H' \nsubseteq H \) for all \( \langle H', T \rangle \in \mathcal{W}' \), or
2. There is \( \langle H', T \rangle \in \mathcal{W} \) such that \( H' \nsubseteq H \) for all \( \langle H, T \rangle \in \mathcal{W} \).

If the former, \( \langle H, T \rangle \in \mathcal{W} \) implies that \( \langle H \cap U, T \cap U \rangle \in \mathcal{W}_U \) and \( \langle H \cap U, T \cap U \rangle \in \mathcal{W}_\mathcal{T} \). Furthermore, \( \langle H \cap U, T \cap U \rangle \in \mathcal{W}_U \) plus \( \mathcal{W} \preceq \mathcal{W}_1 \) imply that there is \( \langle H', T \cap U \rangle \in \mathcal{W}_1 \) such that \( H' \preceq H \cap U \). Let \( H' = H'' \cup (H \cap U) \). Then, \( \langle H', T \rangle \in \mathcal{W}_1 \sqcup \mathcal{W}_\mathcal{T} = \mathcal{W}' \) which is a contradiction.

If the latter, \( \langle H', T \rangle \in \mathcal{W} \) implies that there are \( \langle H'_1, T_1 \rangle \in \mathcal{W}_1 \) and \( \langle H_2, T_2 \rangle \in \mathcal{W}_\mathcal{T} \) such that \( H' = H'_1 \cup H_2 \) and \( T = T_1 \cup T_2 \). Furthermore, \( \langle H'_1, T_1 \rangle \in \mathcal{W}_1 \) plus \( \mathcal{W} \preceq \mathcal{W}_1 \) imply that there is \( \langle H_1, T_1 \rangle \in \mathcal{W}_U \) such that \( H'_1 \subseteq H_1 \). Let \( H = H_1 \cup H_2 \). Then, \( \langle H, T \rangle \in \mathcal{W} \) and \( H' = H'_1 \cup H_2 \subseteq H_1 \cup H_2 = H \) which is a contradiction.

**Lemma 5.** Let \( U \subseteq \text{At} \) be some set of atoms and let \( \mathcal{W} \) and \( \mathcal{W}_1 \) be two belief views such that \( \mathcal{W} \preceq \mathcal{W}_1 \). Then, \( \mathcal{W}_1 \sqcup \mathcal{W}_\mathcal{T} \preceq \mathcal{W} \).

*Proof.* Let \( \mathcal{W}' = \mathcal{W}_1 \sqcup \mathcal{W}_\mathcal{T} \). By definition, \( \mathcal{W} \prec \mathcal{W}_1 \) implies \( \mathcal{W} \preceq \mathcal{W}_U \) and, from Lemma 4, this implies \( \mathcal{W}' \preceq \mathcal{W} \). Furthermore, since \( \mathcal{W} \prec \mathcal{W}_1 \), it follows that there is \( \langle H'_1, T_1 \rangle \in \mathcal{W}_1 \) and \( \langle H_1, T_1 \rangle \in \mathcal{W}_U \) such that \( H'_1 \subseteq H_1 \). In addition, \( \langle H_1, T_1 \rangle \in \mathcal{W}_U \) implies that there is \( \langle H, T \rangle \in \mathcal{W} \) such that \( H_1 = H \cap U \) and \( T_1 = T \cap U \). Let \( H' = H'_1 \cup (H \cap U) \). Then, \( \langle H', T \rangle \in \mathcal{W}_1 \sqcup \mathcal{W}_\mathcal{T} = \mathcal{W}' \) and we can see that \( H' \subseteq H \). Consequently, \( \mathcal{W}' \prec \mathcal{W} \).

**Lemma 6.** Let \( \mathcal{W} \) and \( \mathcal{W}' \) be two belief views such that \( \mathcal{W} \preceq \mathcal{W}' \) and \( U \subseteq \text{At} \) be a set of atoms. Then, \( \mathcal{W}_U \preceq \mathcal{W}'_U \).

*Proof.* Suppose, for the sake of contradiction, that \( \mathcal{W}_U \not\preceq \mathcal{W}'_U \). Then, one of the following hold:

1. There is \( \langle H', T \rangle \in \mathcal{W}'_U \) such that \( H \subseteq H' \) for every \( \langle H, T \rangle \in \mathcal{W}_U \).
2. There is \( \langle H, T \rangle \in \mathcal{W}_U \) such that \( H \subseteq H' \) for every \( \langle H', T \rangle \in \mathcal{W}'_U \).

Assume the former. Then, there is \( \langle H'_1, T_1 \rangle \in \mathcal{W}'_U \) such that \( H' = H'_1 \cap U \) and \( T = T \cap U \). Furthermore, since \( \mathcal{W} \preceq \mathcal{W}' \), this implies that there is \( \langle H, T \rangle \in \mathcal{W} \) such that \( H_1 \subseteq H'_1 \). In its turn, this implies that \( \langle H, T \rangle \in \mathcal{W}_U \) with \( H = H_1 \cap U \) and, it is easy to see that \( H = H_1 \cap U \subseteq H'_1 \cap U = H' \) which is a contradiction with the assumption.

Otherwise, there is \( \langle H_1, T_1 \rangle \in \mathcal{W}'_U \) such that \( H = H_1 \cap U \) and \( T = T_1 \cap U \). Furthermore, since \( \mathcal{W} \preceq \mathcal{W}' \), this implies that there is \( \langle H'_1, T_1 \rangle \in \mathcal{W}' \) such that \( H_1 \subseteq H'_1 \). In its turn, this implies that \( \langle H', T \rangle \in \mathcal{W}'_U \) with \( H' = H'_1 \cap U \) and, it is easy to see that \( H = H_1 \cap U \subseteq H'_1 \cap U = H' \) which is a contradiction with the assumption.
Lemma 7. Let \( W \) and \( W' \) be two belief views such that \( W < W' \) and \( U \subseteq At \) be a set of atoms. Then, \( W_U < W'_U \) or \( W_T < W'_T \).

Proof. From Lemma 6, it follows that \( W_U \not\leq W'_U \) or \( W_T \not\leq W'_T \) holds. Then, it is easy to see that \( W_U = W'_U \) or \( W_T = W'_T \) implies \( W = W' \). Hence, the result must hold.

Proof of Proposition 3. Assume first that \( W \) is an equilibrium epistemic model of \( \Pi \). Then, \( W \) is a total epistemic model of \( \Pi \) and, thus, also of \( \Pi_1 \) and \( \Pi_2 \). From Proposition 10, this implies that \( W_U \) is a total epistemic model of \( \Pi_1 \) and \( W_T \) is a total epistemic model of \( \Pi_2 \). Suppose now, for the sake of contradiction, that \( W_U \) is not an equilibrium epistemic model of \( \Pi_1 \). Then, there is some non-total epistemic model \( W_1 \) of \( \Pi_1 \) such that \( W_1 < W_U \) and, from Proposition 10 again, it follows that \( W' = W_1 \cup W_T \) is a non-total epistemic model of \( \Pi \). Furthermore, it can be checked that \( W' \not< W \) (Lemma 5). This is a contradiction with the assumption and, thus, \( W_U \) must be an equilibrium epistemic model of \( \Pi_1 \). The proof that \( W_T \) must be an equilibrium epistemic model of \( \Pi_2 \) is analogous.

The other way around. Assume that \( W_U \) is an equilibrium epistemic model of \( \Pi_1 \) and \( W_T \) is an equilibrium epistemic model of \( \Pi_2 \). Again, from Proposition 10, this implies that \( W \) is epistemic model of \( \Pi \). Furthermore, if we suppose that \( W \) is not equilibrium epistemic model of \( \Pi \), then there must be some \( W' \not< W \) such that \( W' \) is a non-total epistemic model of \( \Pi \) and this implies that \( W_U \) is epistemic model of \( \Pi_1 \) and \( W_T \) is epistemic model of \( \Pi_2 \) and that either \( W_U \not< W_U \) or \( W_T \not< W_T \) holds Lemma 7. This is a contradiction with the assumption, which implies that \( W \) must be an equilibrium epistemic model of \( \Pi \).

Lemma 8. Let \( \Gamma \) be some theory, \( W \) be some total belief view and \( \varphi \) be some formula such that \( W \vDash K\varphi \) (resp. \( W \nvDash K\varphi \)). Let \( \Gamma' \) be the result of replacing some occurrence of \( K\psi \) by \( T \) (resp. \( \bot \)). Then, \( W \vDash \Gamma \) iff \( W \vDash \Gamma' \).

Proof. It is enough to show that \( W \vDash \varphi \) iff \( W \vDash \varphi' \) for any formula \( \varphi \in \Gamma \). Note that, if \( \varphi \) is a propositional formula, then \( \varphi = \varphi' \) and the result holds. Furthermore, if \( \varphi = K\psi \), we have \( W \vDash K\psi \) and \( W \vDash T \) (resp. \( W \nvDash K\psi \) and \( W \nvDash \bot \)), so the result also holds. Then, the rest of the proof follows by structural induction.

Lemma 9. Let \( \Pi \) be some logic program, \( W \) be some (possibly non-total) belief interpretation and \( a \in At \). Let \( \Pi' \) be the result of replacing some occurrence of \( Ka \) in the body of some rule by \( T \) if \( W \vDash Ka \) and by \( \bot \) otherwise. Then, \( W \vDash \Pi' \) implies that \( W \vDash \Pi \).

Proof. It is enough to prove that any rule \( r \in \Pi \) satisfies that \( W \vDash r' \) implies \( W \vDash r \) where \( r' \) is the result of replacing some occurrence of \( a \) in its body by \( T \). Then, we assume that \( W \vDash r \) and we will show that \( \langle W, H_i, T_i \rangle \vDash r \) for any \( \langle H_i, T_i \rangle \in W \). Note that \( W \vDash r' \) implies \( \langle W, H_i, T_i \rangle \vDash r' \) and, thus, that one of the following conditions hold:

- \( \text{Head}(r') \cap H_i \neq \emptyset \), or
- \( T \in \text{Body}^+(r') \), or
- \( \bot \in \text{Body}^-(r') \), or
- \( \text{Atoms}(\text{Body}^+(r')) \subseteq T_i \), or
- \( \text{Atoms}(\text{Body}^+(r')) \subseteq T_i \) for some \( \langle H_j, T_j \rangle \in W \), or
- \( \text{Atoms}(\text{Body}^-(r')) \cap T_i \neq \emptyset \) or
- \( \text{Atoms}(\text{Body}^-(r')) \cap T_i \neq \emptyset \) for some \( \langle H_j, T_j \rangle \in W \), or
Let $B$, this implies that $K$ references of $B$.

Assume that consequently, $W$ and, thus, we get that $A$ (Lemma 9) and, thus, that $B \prec W$ and that $W$ cannot be an FEEL-world views of $W$.

Hence, there is a subjective literal of the $W$ for some $j$.

This implies that there is some rule $r \in \mathcal{T}_r(\Pi)$ such that $W' \models r_W$ but $W' \models r$. Hence, there is a subjective literal of the form $W$ in the body of $r$ such that $a \in U$ and $W' \not\models a$ but $W' \models K a$. Furthermore, from Proposition 10 and the fact that $W$ and $W'$ are epistemic models of $\Pi$, it also follows that $W_U$ and $W'_{U}$ are epistemic models of $B_U(\Pi)$. Note that, since $a \in U$, we also have $W_U \not\mathcal{W}_{U} (\Pi)$. and, thus, $W_U$ cannot be an FEEL-world views of $B_U(\Pi)$. From Proposition 3, this implies that $W$ cannot be an FEEL-world views of $B_U(\Pi) \cup E_U(\Pi, W)$, which is a contradiction with the assumptions. Consequently, $W$ must be an FEEL-world view of $\Pi$.

**Proposition 4.** First note that $B_U(\Pi) \cup E_U(\Pi, W)$ is the result of replacing the occurrences of $K a$ in $\mathcal{T}_r(\Pi)$ by $\top$ if $W \models K a$ and by $\bot$ otherwise. Furthermore, since $W$ is total, this implies that $W$ is an epistemic model of $\Pi$ if and only if $W$ is an epistemic model of $B_U(\Pi) \cup E_U(\Pi, W)$ (Lemma 8).

Assume that $W$ is an FEEL-world view of $\Pi$ and suppose, for the sake of contradiction, that $W$ is not an FEEL-world view of $B_U(\Pi) \cup E_U(\Pi, W)$. Then, there is some non-total epistemic model $W'$ of $B_U(\Pi) \cup E_U(\Pi, W)$ such that $W' \not\mathcal{W} W$, but this implies that $W'$ is also an epistemic model of $\Pi$ (Lemma 9) and, thus, that $W$ is not an FEEL-world view of $\Pi$. This is a contradiction and, consequently, $W$ must be an FEEL-world view of $B_U(\Pi) \cup E_U(\Pi, W)$.

Assume now that $W$ is an FEEL-world view of $B_U(\Pi) \cup E_U(\Pi, W)$ and suppose that $W$ is not an FEEL-world view of $\Pi$. Then, there is some non-total epistemic model $W'$ of $\Pi$ such that $\not\mathcal{W} W$ and that $W'$ is not an epistemic model of $B_U(\Pi) \cup E_U(\Pi, W)$. This implies that there is some rule $r \in \mathcal{T}_r(\Pi)$ such that $W' \not\models r_W$ but $W' \models r$. Hence, there is a subjective literal of the form $K a$ in the body of $r$ such that $a \in U$ and $W' \not\models K a$ but $W' \models K a$. Furthermore, from Proposition 10 and the fact that $W$ and $W'$ are epistemic models of $\Pi$, it also follows that $W_U$ and $W'_{U}$ are epistemic models of $B_U(\Pi)$. Note that, since $a \in U$, we also have $W_U \not\mathcal{W}_{U} (\Pi)$. and, thus, $W_U$ cannot be an FEEL-world views of $B_U(\Pi)$. From Proposition 3, this implies that $W$ cannot be an FEEL-world views of $B_U(\Pi) \cup E_U(\Pi, W)$, which is a contradiction with the assumptions. Consequently, $W$ must be an FEEL-world view of $\Pi$.

**Proposition 11.** Let $\phi$ be a formula and let $\langle W, H, T \rangle$ be an interpretation. Then, $\langle W, H, T \rangle \models \neg \phi$ iff $\langle W', T, T \rangle \not\models \phi$ iff $\langle W', T, T \rangle \models \neg \phi$. 

\[\square\]
Proof. By definition, we have that \( \langle W', T, T \rangle \models \neg \varphi \) iff \( \langle W', T, T \rangle \not\models \varphi \). Furthermore, by definition, we have that \( \langle W, H, T \rangle \models \neg \varphi \) iff both \( \langle W, H, T \rangle \not\models \varphi \) and \( \langle W, T, T \rangle \not\models \varphi \). Finally, since Proposition 1 in (Cabalar et al. 2019a), we have that \( \langle W, H, T \rangle \models \varphi \) implies \( \langle W, T, T \rangle \models \varphi \) we get that \( \langle W, H, T \rangle \models \neg \varphi \). \]

\[ \]

Proposition 12. Given a theory \( \Gamma \) and, a belief interpretation \( \langle W, H, T \rangle \) is a belief model of \( \Gamma \) iff \( \langle W, H, T \rangle \) is a belief model of \( \Gamma^{\text{FAEEEL}} \).

Proof. Pick a formula of the form \( \neg K \varphi \). Then, from Proposition 11, it follows \( \langle W, H, T \rangle \models \neg K \varphi \) iff \( \langle W, T, T \rangle \not\models \varphi \) if \( W \not\models \varphi \) if \( W \not\models K \varphi \) iff \( W \not\models K \varphi \) if \( W \not\models (K \varphi) \) \( W \) \( \models W \) \( \models \top \) \( \langle W, H, T \rangle \models \neg \varphi \). The rest of the proof follows by induction.

Proof of Proposition 6. From Proposition 12, it follows that \( \langle W, T \rangle \) is an equilibrium belief model of \( \Gamma \) iff \( \langle W, T \rangle \) is a belief model of \( \Gamma^{\text{FAEEEL}} \). Hence, it immediately follows that \( W \) \( \models \text{FAEEEL} \)-world view of \( \Gamma \) iff \( W \) \( \models \text{FAEEEL} \)-world view of \( \Gamma^{\text{FAEEEL}} \). \]

Proof of Proposition 7. Let \( W \) be a total belief model of \( \Gamma \) and \( W' \) be a simple belief model of \( \Gamma \). Then, it is enough to show that \( W' \preceq W \) iff \( W = (W')' \) and there is some \( \langle H, T \rangle \in W' \) satisfying \( H \subseteq T \). Assume first that \( W = (W')' \) and there is some \( \langle H, T \rangle \in W \) satisfying \( H \subseteq T \). Then, \( W \models (W')' \) implies

(i) for every \( \langle T, T \rangle \in W \), there is some \( \langle H, T \rangle \in W' \) with \( H \subseteq T \), and

(ii) for every \( \langle H, T \rangle \in W' \), there is some \( \langle T, T \rangle \in W \) with \( H \subseteq T \).

Hence, \( W' \preceq W \). Furthermore, since \( W \) is total and there is some \( \langle H, T \rangle \in W \) satisfying \( H \subseteq T \), it follows that \( W' \neq W \) and, thus, \( W' \preceq W \). The other way around, \( W' \preceq W \) implies \( W' \preceq W \) and, thus, that both (i) and (ii) hold. In its turn, this implies \( W = (W')' \). Furthermore, since \( W \neq W' \), either there is some \( \langle T, T \rangle \in (W \setminus W') \) or some \( \langle H, T \rangle \in (W' \setminus W) \). If the former, from (i), there is \( \langle H, T \rangle \in W' \) with \( H \subseteq T \). Moreover, since \( \langle T, T \rangle \notin W' \), it immediately follows that \( H \subseteq T \). If the latter, there is some \( \langle T, T \rangle \in W \) with \( H \subseteq T \) and, since \( \langle H, T \rangle \neq W \), that \( H \subseteq T \). \]

Proof of Proposition 8. Suppose not. Then there is a some program \( \Pi \), belief view \( W \) and some subjective constraint \( r \) such that the following equivalence does not hold:

\[ W \) \models \text{FAEEEL} \)-world view of \( \Pi \) iff \( W \) \( \models \text{FAEEEL} \)-world view of \( \Pi \) and \( W \models r. \)

Assume first that \( W \) \( \models \text{FAEEEL} \)-world view of \( \Pi \) \( \cup \) \{\( r \)\}. Then, \( W \) \( \models \) the non-empty set of all stable models of \( \Pi \) \( \cup \) \{\( r \)\} \( W \) \( = \Pi \) \( W \) \( \cup \) \{\( r \)\} \( W \), that is, \( W = \text{SM}[\Pi \} \cup \{r \} \) \( W \) \( \neq \emptyset \). Furthermore, we can see that \( W \) \( = \text{SM}[\Pi \) \( W \) \( \cup \{r \} \) \( W \) \( \subseteq \text{SM}[\Pi \) \( W \) \) implies that every \( M \in W \) satisfies \( M \models r \) \( W \). Let \( r \) be of the form:

\[ \bot \leftarrow K a_1 \land \ldots \land K a_n \land \neg K b_1 \land \ldots \land \neg K b_m \quad (A1) \]

and suppose, for the sake of contradiction, that \( r \) \( W \) is of the form:

\[ \bot \leftarrow a_1 \land \ldots \land a_n \quad (A2) \]

Then, for all \( 1 \leq i \leq n \), we get \( W \models K a_i \) and, thus, every \( M \in W \) satisfies \( M \models a_i \). However, this implies every \( M \in W \) does not satisfy \( r \) \( W \), which is a contradiction with the fact that \( M \) \( \models \) a stable model of \( \Pi \) \( W \) \( \cup \{r \} \) \( W \). Hence, it must be that \( W \models K a_i \) for some \( 1 \leq i \leq n \) or \( W \not\models K a_j \) for some \( 1 \leq j \leq m \) and, thus, \( W \models r \). Furthermore, this implies that \( \{r \} \) \( W \) \( = \emptyset \) and, thus, that
\[ \Pi^W \cup \{r\}^W = \Pi^W. \] Consequently, we get that \( W = SM[\Pi^W \cup \{r\}^W] = SM[\Pi^W] \)

The other way around. Let \( W \) be a G11-world view of \( \Pi \). Then, since \( W \models r \), it follows that \( \{r^W\} = \emptyset \) and, thus \( SM[\Pi^W \cup \{r\}^W] = SM[\Pi^W] = W. \) \[ \square \]
